Depending on the emphasis a theory places on transmission or interaction results a completely different picture of what is "communication", "information" or "reality". These approaches are in fact complimentary and would enhance each other's reach and analytic potential if integrated.

As we have stated before, 'information,' 'communication' and 'social interaction' are inextricable elements of the production of meaning. By denying the pragmatic dimension of communication (reducing communication phenomena to the 'content' – or information) makes it easier for a researcher to analyse (as the avoidance the pragmatics would certainly reduce complexity). However, this reduction will have a cost: as we have seen, when pragmatics is not considered, there is a loss of meaning, this reduction causes the phenomenon to 'disappear'.

The transmission and social perspectives are not contradictory, but complementary. To emphasize the relational perspective is to value the idea that communication is human action, made by people. Under ethnographic perspective, it is possible to observe values and principles of a system in place being contradicted or reversed, through social resilience and creative subversions of the industrial prescriptions. (Braga and Logan, 2014) This perspective stresses that communication problems are "community issues", which relate to the communities that they have created and in which we live.

Thus we conclude that the processes of 'transmission of information' and communication are not same. Communication requires that the information that is transmitted, which is only a signal after all, must be processed within the ground of pragmatics or social context. Put simply communication is contextualized information contextualized through pragmatics and social interactions.

KEY TERMS AND DEFINITIONS

Communication: A symbolic process whereby the social reality is produced, understood, maintained and updated in a given situation. Communication is the mediation that allows collective social action. Communication is contextualized information through pragmatics.

Data: The pure and simple facts without any particular structure or organization, the basic atoms of information.

Information: Structured, organized data. It is composed by syntax and semantics, that is, with reference to a code and to a given meaning.

Knowledge: The ability to use information strategically in a social context to achieve one's objectives.

Naturalistic Perspective: Empiricist approach of the Social Sciences based on the premise of collecting data essentially from “natural” situations, those that happen despite of the presence or participation of the researcher.

Pragmatics: A discipline that stands between Philosophy and Linguistics, and tries to define to which degree the human sense of 'reality' is determined by language. The production of meaning is oriented to action, and that the idea of what a thing 'is' lies on the sum of the effects that can be conceived as possible from it. Pragmatics is the use of social context to assist meaning.

Social Interaction: Mutual action and/or influence among co-participants of the same social situation.

Wisdom: The capacity to choose objectives consistent with one's values and within a social context.

Data Journalism

Andreas A. Veglis

Aristotle University of Thessaloniki, Greece

Charalampos P. Bratsas

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The introduction of ICTs (Information Communication Technologies) had a profound impact on every aspect of human activities. In the case of journalism, the utilization of ICTS has transformed the profession through the digitalization of the work process as well as the introduction of the internet along with its services (Veglis 2009). Today the journalist is expected to have the ability to firstly employ many tools and services in order to be instantly informed about breaking news as well as current events, and secondly, use a variety of tools and applications in order to prepare and disseminate news articles (Veglis & Bratsas, 2017). Many new types of journalism have emerged, among which, data journalism (Gray, Chambers, & Bounegru, 2012), which requires journalists to have special ICT skills.

In the recent years, data journalism has drawn significant attention in the academic literature as well as in the area of new developments in digital news production (Appelgren & Nygren, 2014; Fink & Anderson, 2015; Mair & Keeble, 2014). Data journalism is considered to be a new form of journalism. It has appeared gradually in the dawn of the new century. Many factors have contributed to the introduction of data journalism, but one of the most prominent is believed to be the availability of data in digital form (Veglis & Bratsas, 2017). Data Journalism is a journalistic specialty reflecting the increased role of the numerical data has in the production and distribution of information in the digital era. Data can be the source of data journalism, and/or it can be the tool

with which the story is told (Gray, Chambers, & Bounegru, 2012).

This chapter examines current trends and future perspectives of data journalism. The background section provides historic evolution and definitions of data journalism. Next, the stages of data journalism are presented in detail. Also, the relation between data journalism and open data is discussed due to the importance of the later in the development of data journalism. Finally, recommendations and future research direction are briefly discussed.

BACKGROUND

Evolution and Definition

Although the term data journalism started to attract attention at the end of the previous century, initial examples of data journalism appeared quite early. According to Simon Rogers the first example of data journalism was published at Guardian in 1821. It concerned the number of students who attended school and the costs per school in Manchester (Gray, Chambers, & Bounegru, 2012).

At the end of the 20th century, employing large data to write an article was difficult and required skills that went beyond the capabilities of the average journalist. That resulted in the phenomenon that some news organization in the United States and Great Britain were hiring programmers that worked on novel news products (Parasied & Dagiral, 2013). Traditionally, journalists used to rely on information provided by various sources

(governments, officials, research studies, etc.). Of course, there were some cases of investigative journalism where journalists were able to find resources to gather and analyze their own data and publish their results in articles (Veglis & Bratsas, 2017). But as a growing amount of data gradually became available online, and efficient tools with which anyone can analyze, visualize and publish large amounts of data appeared, things changed significantly (Sirkkunen, 2011).

The concept of data journalism is not new. It has been around since the beginning of the digitalization. Digital data has been utilized in news production since the late 60s in US newspapers (Parasied & Dagiral, 2012). Data journalism gradually emerged with the rapid introduction of ICTs and the availability of data in digital form. The term data journalism is synonymous with data-driven journalism while the older term, computer-assisted reporting has vanished since it was introduced at the early stages of computer history (Bradshaw, 2010). It is worth noting that in the case of data journalism there is an increased interaction between journalists and several other fields such as design, computer science and statistics (Thibodeaux, 2011; Veglis & Bratsas, 2017).

The term data journalism is attributed to Simon Rogers that first mentioned it in a post to the Guardian Insider Blog (Knight, 2015). It can be viewed as a process that begins with analyzing, and continues with filtering and visualizing data in a form that links to a narrative (Lorenz, 2010). It combines spreadsheets, graphics data analysis and the biggest news stories (Rogers, 2008). It is fundamentally the production of news graphics and includes elements of design and interactivity (Bradshaw, 2010; Lorenz, 2010; Rogers, 2008). Megan Knight (2015) describes data journalism as “a story whose primary source or “peg” is numeric (rather than anecdotal), or a story which contains a substantial element of data or visualization”.

Veglis and Bratsas (2017) proposed a definition in order to better address the power of visualization and interactivity that are significant factors in data journalism. They defined data journalism

as the process of extracting useful information from data, writing articles based on the information and embedding visualizations (interacting in some cases) in the articles that help readers understand the significance of the story or allow them to pinpoint data that relate to them.

Journalists' Skills

Today the journalist is expected to possess various ICT skills in order to cope successfully with the challenges in his everyday work (Veglis & Bratsas, 2017). Typical examples are writing news articles, constructing diagrams via spreadsheet applications, communication via e-mail, visualizing data with the help of various applications, publishing material on the WWW (Peebles 2011). Also, they often seek information on the web and by e-mail (Veglis, 2013). Veglis and Pomportsis (2012, 2014) organized the journalists' ICT skills into five categories, namely *Basic skills*, *Web publishing skills*, *Web 2.0 skills*, *Web casting skills* and *Data Journalism skills*. Veglis & Bratsas (2017) extended this categorization by adding a category that refers to *Web 3.0*. Next, the six categories are briefly presented:

- **Basic Skills:** The journalist has the ability to work efficiently with office automation suites (which include word processing, spreadsheet, presentation, database), and with the basic Internet services (WWW, email). Specifically, the journalist is expected to have basic typing and formatting skills, and he must be able to perform basic functions in a spreadsheet. He must have at least a general understanding of how to use data to support news stories and he must also be able to use relational database programs to cross-check those data files to find various information (Veglis & Pomportsis, 2014).
- **Web Publishing Skills:** In this case, basic knowledge of HTML is considered to be a necessary prerequisite, as well as the abil-

ity to use Content Managements Systems. The journalist should have an understanding of the basic concepts of HTML and cascading styling sheet (CSS) (Peebles, 2011). Except web publishing, the journalist must be able to work with widely used Desktop Publishing Applications (Veglis & Pomportsis, 2014).

- **Web 2.0 Skills:** Web 2.0 includes the utilization of various tools and services such as blogs, RSS, wikis, social bookmarking, and social networking (Facebook, Google+, Twitter, etc.). The journalist must be able to update the media organization's profile on social networks, and also to interact with the audience through various services, such as blogs, Twitter, Facebook, Google+, etc. (Veglis & Pomportsis, 2014). It is worth noting that the majority of the Web 2.0 tools and services can also be used by the journalists in order to receive updates on current events from various news organizations.
- **Webcasting Skills:** In this case journalists must have the necessary skills to create and publish podcasts and videocasts. The journalist must be able to record the audio of an interview, perform simple editing on the audio recording of that interview, and upload it to the WWW for the audience to have access to the podcast. In the case of videocasts, the journalist must be capable of making, at least, a short video story even if it is shot with a smartphone and must have the skills of using entry-level nonlinear video editing software, to move

scenes around, to create a basic news video (Fletcher, 2008). Podcasts are considered to be an effective way to use audio to broadcast news stories since they are easy to create and their size is relatively small. Videocasts are considered to be powerful tools to convey news, but they are more difficult to create in comparison with podcasts and their sizes are quite large (Veglis & Pomportsis, 2014).

- **Web 3.0 Skills:** Include basic knowledge and experience with Web 3.0 technologies. Journalists must be able to a) understand the basics of Web 3.0, b) use the limited Web 3.0 tools currently available (but expected to grow exponential in the near future) c) create articles that comply with open data rules and link to other open data (Veglis & Pomportsis, 2014).
- **Data Journalism Skills:** Journalists must be able to find datasets, clean and filter the data, put them in context, find the story in the data, visualize the results and integrate them into a news story (Veglis & Bratsas, 2017).

DATA JOURNALISM STAGES

Veglis and Bratsas (2017) organized the data journalism workflow in six stages, entitled: *Data Compilation*, *Data Cleaning*, *Data Understanding*, *Data Validation*, *Data Visualization* and *Article Writing*. The workflow model is depicted in figure 1. Next, we briefly describe each stage.

Figure 1. Data journalism workflow

- **Data Compilation:** A data journalism project begins in one of two ways: either the journalist has a question that needs data, or a dataset that needs questioning. The compilation of data can take one of the following forms: (i) data may be supplied directly by an organization (in some cases in the form of open data), (ii) data may be found with the help of advanced searching techniques, (iii) data may be compiled by scraping web pages, (iv) data may be collected by converting documents to other formats that can be analyzed, and (v) data may be collected by means of observation, surveys, online forms or crowdsourcing (Bradshaw, 2011). Data scraping is a process in which a software tool extracts data from a human-readable output that originates from other software. Also, there are free tools on the internet that allow users to convert documents to other forms that can be analyzed. For example, DocumentCloud is a web-based software platform created specifically for journalists to allow the searching, analyzing, annotation and publication of primary source documents used in reporting (Veglis & Bratsas, 2017).
- **Data Cleaning:** Also known as data scrubbing is the process of detecting and correcting corrupted or incorrect records from a dataset (Wu, 2013). This can be accomplished by removing human errors and converting the data into a format that is consistent with other data the journalist is using. Typical examples include empty entries, duplicate entries, the use of default values to save time or where no information was held, incorrect formatting (for example words instead of numbers), corrupted entries or entries with HTML code, multiple names for the same thing and missing data (Bradshaw, 2011). Cleaning data can be done in simple ways, for example using find and replace commands or filters in spreadsheets. There are also specialized tools, like Google's OpenRefine, which is a standalone open source desktop application for data cleanup and transformation to other formats. The application's interface resembles spreadsheet applications and it can open files of various spreadsheet formats (Veglis & Bratsas, 2017).
- **Data Understanding:** Datasets usually include various codes that represent categories, classifications or locations, and special terminology that it is not understood by journalists. Frequently further data is required in order for existing data to become meaningful. Overall journalists must be data-literate, meaning that they must be able to consume knowledge, produce coherently and think critically about data (Veglis & Bratsas, 2017). Additionally, journalists must possess statistical knowledge and also understand how to work with large datasets, how they were produced, how to connect various datasets and how to interpret them (Gray, Chambers, & Bounegru, 2012).
- **Data Validation:** This stage includes the process of cross-checking the original data and obtaining further data from sources in order to enrich the available information (Silverman, 2014; Veglis, 2013). It is worth noting that like any source, datasets cannot always be trusted since they come with their own histories, biases, and objectives. That means that journalists have to investigate issues like: who gathered it, when, and for what purpose, and how it was gathered (Bradshaw, 2011). This can be accomplished by investigating the history of the creation of the dataset, by finding references to the dataset or by using other sources of information that refer to the same subject (Silverman, 2014; Veglis & Bratsas, 2017).
- **Data Visualization:** Data visualization is a modern branch of descriptive statistics that involves the creation and study

of the visual representation of data. It is the graphical display of abstract information for data analysis and communication purposes (Cairo, 2012). Static data visualizations offer only pre-composed “views” of data. Interactive data visualization supports multiple static views in order to present a variety of perspectives on the same information. Important stories include “hidden” data and interactive data visualization is the appropriate way to discover, understand and present these stories. In interactive data visualization, there is a user input (a control of some aspect of the visual representation of information) and the changes made by the user must be incorporated into the visualization in a timely manner (Veglis, 2015; Veglis & Bratsas, 2017).

It is worth mentioning that infographics are also part of the static visualization. Infographics are graphic visual representations of data or knowledge, which are able to present complex information quickly and clearly (Smiciklas 2012). They are often used in newspapers, to show the weather, as well as maps, site plans, and graphs for statistical data (Veglis & Bratsas, 2017).

There are many types of data visualizations. Heer, Bostock, and Ogievetsky (2010) defined the types (and also their sub-categories) of data visualization: (i) Time-Series Data (Index Charts, Stacked Graphs, Small Multiples, Horizon Graphs), (ii) Statistical Distributions (Stem-and-Leaf Plots, Q-Q Plots, Scatter Plot Matrix -SPLOM, Parallel Coordinates), (iii) Maps (Flow Maps, Choropleth Maps, Graduated Symbol Maps, Cartograms), (iv) Hierarchies (Node-Link Diagrams, Adjacency Diagrams, Enclosure Diagrams) and (v) Networks (Force-Direct Layout, Arc Diagrams, Matrix Views).

Today there are a lot of available online tools that can be used for creating interactive data visualizations. All of them are either free or offer a free version (except a paid one that includes more

features). Some of the most widely used tools are CartoDB, Google Chart Tools, Google Fusion Tables, Tableau Public, Many Eyes, and Infogr.am. A complete list of the available tools can be found at <http://selection.datavisualization.ch>.

Article Writing: The last stage in a data journalism project includes the writing of the news article. Depending on the intended publication medium, the article may include special characteristics (for example external links other articles or related material, multimedia content, mashups, static or interactive visualizations) in order to fully take advantage of the medium’s potentials (Veglis & Bratsas, 2017). The amount of text that is included in the data journalism article along with the visualizations may vary considerably. Specifically, we can have the case where the visualization supplements the text (which is quite extended) as well as the case where the visualization is the center of the project and the text plays a supplemental role, explaining parts of the visualization.

FUTURE RESEARCH DIRECTIONS

Tim Berners-Lee believes that “data-driven journalism is the future” and urges reporters to hunt for stories in datasets (Arthur, 2010). We are convinced that the Semantic Web and Linked Open Data will play a significant role in the evolution of data journalism. In the future, journalists should be able to comprehend and utilize advanced technologies which will include more “intelligent web” (Bradshaw & Rohumaa, 2011). Semantic Web technologies, smart devices (smartphones etc.) and tools are continuously being transformed and upgraded. Data journalism ought to adopt these technologies. It is worth noting that Web 3.0 and open data can play an important role in the case of data journalism as they support the acquisition and validation of data which are the main source of data journalism.

Tim Berners-Lee, the inventor of the Web and Linked Data initiator developed a 5-star deployment scheme for Open Data, in order to encourage

Figure 2. Star rating system for the use of good linked open data for journalists

people – especially government data owners to produce well linked Open Data (2010). Veglis and Bratsas (2017) proposed an adaptation of the system for the journalists in order to act as a guide for them to produce articles in the Web 3.0 era. The star rating system is presented in figure 2 and includes the steps that a journalist can take in order to accomplish good Web 3.0 practices in journalism.

One other issue that needs to be addressed is the lack of online platforms that can support all stages of a data journalism project. Today there are several online tools that can be used in different stages of a data journalism project. Each tool has its own unique interface and the journalist must spend time in order to learn how to use it effectively. The majority of them do not offer any interconnectivity with other tools. Thus, the jour-

nalist spends a lot of time in order to transfer data from one platform to another in order to exploit the strong points of each tool. Data journalists can strongly benefit from the introduction of an online platform that will interface various online tools that can be used in data journalism projects.

**it is a string of characters used to identify a name of a resource over the WWW. The most common form of URI is the uniform resource locator (URL), frequently referred as a web address.*

CONCLUSION

This chapter discusses the issue of data journalism. Data journalism is considered to be a journalistic specialty that is expected to flourish in the world

of data that we are living today. Data journalism stages were presented and discussed in detail. These stages define the skills that a journalist ought to possess in order to develop data journalism projects.

The above findings can guide journalism educators in order to adapt their programs. This is already happening since the constant changes in market demands, as far as journalistic skills are concerned, has forced journalism educators to adjust their programs in order to better facilitate the needs of the industry (Wenger & Owens, 2012). Currently data journalism is taught in a limited number of journalism schools in Europe. Of course this is something worth investigating more thoroughly in the near future. A recent survey, concerning the use of data journalism in Greece, found a low penetration of data journalism practices in media organizations. Nevertheless the majority of the journalists appeared to agree with the importance of working with data and was interested in acquiring more knowledge and skills concerning data journalism (Veglis & Bratsas, 2017).

There is no doubt that the majority of the journalists today are not involved in data journalism projects, although they are willing to work on such projects in the future. Online journalists appear to be more involved and more motivated towards data journalism and since there is an ongoing shift to online journalism (Cokley, Edstrom, McBride, & Ranke, 2015), we have to expect many new developments in the area of data journalism.

KEY TERMS AND DEFINITIONS

Data Journalism: The process of extracting useful information from data, writing articles based on the information and embedding visualizations in the articles that help readers understand the significant of the story or allow them to pinpoint data that relate to them.

Dataset: A collection of data that contains individual data units organized in a specific way and accessed by a specific access method that is based on the data set organization.

Data Scraping: The process in which a software tool extracts data from human-readable output that originates from other software.

Data Cleaning or Data Scrubbing: The process of detecting and correcting corrupted or incorrect records from a dataset.

Data Validation: The process of cross-checking the original data and obtaining further data from sources in order to enrich the available information.

Data Visualization: The graphical display of abstract information for data analysis and communication purposes.

Open Data: Data that can be freely used, re-used and redistributed by anyone - subject only, at most, to the requirement to attribute and share alike.

Investigating Diachronic Variation and Change in New Varieties of English

Rita Calabrese

University of Salerno, Italy

BACKGROUND

The Study of Indian English From a Language-Contact Perspective

The issue of contact instantiating processes of pidginization and creolization can be differentiated according to varieties that arise through contact with languages coming outside the area, especially through colonialism and varieties that arise through internal contact among languages already indigenous to the area (Schiffman 2010, p.741). From this perspective, the South-Asian region can be considered a paradigm example of the phenomenon known as “convergence area” (Weinreich 1958) referred to phenomena specifically occurring in language contact situations that lead to changes in all areas of grammar.

Some decades after Weinreich’s descriptive study, Charles Ferguson (1992) published a comprehensive essay on some features of “language use” that make South Asia an interesting subject of study as “sociolinguistic area”. His attention to “shared patterns of use” and not only of shared grammatical structures was an important step towards the understanding of general processes of language change in contact situations. Ferguson’s particular perspective, in fact, “looks for the relationship between diachronic language change and language development, phonology and syntax, social conventionalization and cognitive processing, and language universals and individual differences” (Huebner 1996, p.12). Consequently, in studies concerning the development of new varieties, a crucial issue is the extent to which

universals of language (Pinker 2003, p.23) and language contact exert their influence on shaping those language systems. Recent research has tested current hypotheses on the interrelationship between language universals and language variation and given rise to new challenging theories on contact varieties. Namely, the notion of “vernacular universals” (Chambers 2004) limits the supposed tendency towards the *absolute creativity* of these varieties relying on the identification of universally shared features across varieties of English around the world.

The Study of Indian English From a Comparative Perspective

To date, two important issues have not been exhaustively examined by experts in the field of variationist studies: the first deals with the characterization of Standard English at the time of colonization that was slightly different from today’s standard against which new varieties of English are usually investigated, the second concerns possible internal and deterministically governed developments occurring in both early / late Modern English and its new emerging varieties¹.

When considering the peculiar contact situation in the Asian subcontinent English has played a major role in influencing local South Asian languages, though it was not the first European language to have an impact on them since Portuguese was already attested in the area before the founding of the East India Company in the early 1600s. By the end of the 18th century, the knowledge of English had grown greatly and re-

placed Portuguese as the *lingua franca* of India (Nihalani 2005, vi). However, it is worth noting that the *General Report on the Census of India, 1891* still records a low average percentage (4.4%) of ‘those who know English’ (Baines 1893: 224) and “not anyone who learned English in India was taught directly by a native speaker of the language” (Nihalani 2005, vi). Moreover, the local British community is at that time supposed to be expanding to what Schneider (2007, p. 37) defines as “British plus: genuinely British no doubt, but seasoned with the additional flavor of the colonial experience which those who stayed ‘home’ do not share”. ‘Colonial lag’ is the expression used to refer to the consequent conservatism in colonial varieties as a potential factor in distinguishing them ‘from their home counterparts in all levels of language’ (Bauer 2002, p. 5). Overall, some features of a colonial dialect can be predicted from the form used by the majority of the settlers (Bauer, 2002, p. 11) who, in the case of India, came originally from the city of London (Salaja 2009, p. 95)². Anyway, ‘in the colonial situation, a lot of speakers of many different dialects come face to face, and in the short term the result is a period of diversity where everyone is accommodating to everyone else [...]. In most cases the form used by the majority will be the form that survives in the new mixed dialect’ (Bauer 2012, p. 8).

The Emergence of a New Variety

Apart from deviations and occasional ‘errors’, it is therefore possible to classify the features of IndEng into three groups (Meshtrie & Bhatt 2008, p. 47):

1. Dialect features of the superstrate which have survived despite the norms of instructed English
2. Features of early modern English surviving in a particular colony
3. ‘True’ innovations in IndEng with no equivalent forms in modern English.

Some of the possible effects of these factors on the characterization of the emerging variety can be seen in Table 1. Significantly, when comparing the number of innovations characterizing IndEng and late Modern English, the distance between them dramatically reduces at least for some of those aspects that are generally considered as Indian English-specific (Calabrese 2012, 2015).

In particular, the increase in Verb + particle combinations⁴ within the class of multi-word verbs, made up of a common verb, often one syllable combined with a preposition, has been considered as one of the most important characteristics of the modern English vocabulary (Baugh & Cable 2002, p. 345). As a matter of fact, the changing uses of prepositions clearly reflect the idiomatic changes⁵ in a language from one age to another (ibid., p. 248) following the developmental path from synthetic⁶ to analytical constructions. This steady process dating back to Old English led to a gradual structural shift “from a productive system of verbal prefixes to a new system of post-verbal particles [in which] phrasal verbs as well as prepositional verbs come to be the functional equivalents of the older prefixed verbs” (Brinton 1988, p. 185). The same tendency to favor phrasal verbs instead of simplex verbs to express aspectual meanings can frequently be observed in contact situations as well (Danchev 1992, p. 30). The resulting poly-verbal constructions represent a type of paraphrase that has been

Table 1. Linguistic features emerging in Late Modern English and Indian English

Linguistic feature	Late Modern English	Indian English
Increase in Verb+particle combinations	✓	✓
Extensive use of Verb+particle combinations as nouns	✓	✓
Tendency to eliminate 3 rd pers –s marking of <i>do</i> ³	✓	✓
Lexical expansion (borrowings, loanwords, neologisms)	✓	✓

described as an ‘achievement strategy’ that helps communication when the semantic components of a lexical gap in the interlanguage are rearranged linearly and made explicit through separate free morphemes (Danchev, 1992).

Earlier research (Sorace 2005; Calabrese 2008, 2010) on the interpretation of prepositional phrases (PPs) as adjuncts or arguments of verb phrases in Second Language Acquisition (SLA) had highlighted the difficulty by second language learners to automatically integrate syntactic knowledge and information from other domains of language (e.g. morphology and semantics). As a result, the most discriminative feature in determining the choice of a given preposition proved to rely on semantic factors directly depending on the class of the verb. The logical form associated with a given verb is supposed to enhance the interpretation and production of verbs with similar logical forms and sub-categorization frames (Calabrese 2010: 58). For example, the verb *provide* belongs to the same semantic domain as *give* so that the same sub-categorization frame and logical form are assigned to it in the process of SLA leading to deviant forms such as **provide to* attested in IndEng.

A CASE STUDY

The concepts outlined so far and the related methodologies of investigation have provided the rationale for the present preliminary study aiming to diachronically investigate the development of new verb-particle combinations in spoken or speech-like data. Following a corpus-driven approach to the analysis of data, a sample diachronic corpus of Indian English has been queried in order to investigate the structural properties of this new variety from a diachronic perspective. Indeed, the study is based on the assumption that looking backwards at past stages of language development will contribute to identify convergence phenomena over time and gradually reconstruct the shape of a new variety as a standardized language. In

particular, the main focus will be on changes in the lexico-grammar interface which shows more gradient properties typical of structural nativization (Schneider 2007).

Since a key aspect of corpus design for most studies concerning diachronic variation is including the range of linguistic variation that exists in a language in a given historical period and not the proportions of variation (Biber et al. 1998, p.247), a stratified approach has been adopted by sampling data from different genres and time periods to study the frequency and use of verb-particle constructions as a structural property of IndEng rather than an effect of its ‘deviant use’ of English.

METHOD

Materials

The corpus, on which the present study is based, combines data of the Diachronic Corpus of Indian English (henceforth DiCIE)⁷ covering the years from 1835 to 2010 and parallel selected sections of the Indian component of the International Corpus of English (ICE-IND) dating back to 1978. The corpus has been designed on the model of both ICE-IND (Greenbaum 1996) and the Corpus of Contemporary Indian English (CCIE, Balasubramanian 2009) so that the final version of the entire corpus will have a comparable, balanced configuration with respect to the model corpora considered in the research. The corpus contains printed editions of the Indian national newspaper *The Statesman* that were copied from microfilms of the 19th century issues and are part of the British Library Newspaper Collection.

For the purpose of this preliminary study, certain sections of ICE-IND including spoken data such as speeches, reported legal cross-examinations and written data such as letters⁸ to the editor (tagged as <S>, <LCE>, <LE> respectively) have been selected in order to be compared to similar samples from the DiCIE.

More specifically, the spoken data includes audio files of Gandhi (<GANDH-S>), the past Prime Minister Singh (<SINGH-S>) and the MP Lalu Prasad's (<LP-S>) speeches sampled for the years 1930-47 and 2010 respectively⁹.

Procedure

The sections of the corpus including <LCE> and <LE> were created by converting in electronic format the printed texts published in *The Statesman* between the years 1835-1951.¹⁰ The oral data derive from audio/video files available online along with their transcriptions convertible in .txt files to make them readable by concordancers and annotation tools. The collected data were automatically parsed by using the language analysis tools available at the VISL website (<http://beta.visl.sdu.dk/>). The parsers provided by the VISL interface are based on the theoretical framework of the *Constraint Grammar*, a methodological paradigm widely adopted in *Natural Language Processing* (NLP) which can provide both syntactic and semantic information on a given constituent structure by assigning tags of lemmatization, inflection, derivation, syntactic function, constituent dependency, valency, semantic classification. The system also marks the *dependency relations* between parts of speech (POS) with the symbol @ placed before (>) or after (<) the head and proves therefore to be particularly useful for investigations on lexico-grammatical and morpho-syntactic patterns in specific variety usage. Upper case tags describe word classes as well as morphological inflection (e.g. MV= main verb, PRP= preposition, N = noun, GN= genitive). Once annotated, the corpus can be therefore queried for specific tags using a concordancer to find out possible examples of convergence or divergence from the standard usage in the variety under investigation.

Verb-particle combinations were searched for in the corpus and then mapped onto VISL tags by observing the constituent structure of the Verb Phrases and the Prepositional Phrases along with their functional categories. In order to accurately

classify and estimate all MV+PRP occurrences in the annotated corpus, a specific syntactic setting was established in the queries and all examples of MVs occurring with PRPs as their right collocates could easily be extracted. The features examined in the study and the corresponding VISL tags are shown in Table 2. As an example, the following tags have been searched for in order to study the frequency of Verb-particle combinations (tagged as PIV) as well as verb + adjunct constructions (tagged as ADVL) in Indian English.

Examples (1) and (2) show different annotations for different functional interpretations of the PPs in the annotated corpus.

In example (1) the PERS pronoun [*him*] is annotated as an argument of the preposition (P) on the left (@P<, while the prepositional phrase [*upon him*] is annotated as an adjunct/free adverbial.

- (1) They[they] PERS 3P NOM @SUBJ> immediately[immediately] ADV @ADVL> **sprung**[spring] <mv> V PCP2 PAS @ ICL-N< **upon** [upon] **PRP** @<**ADVL** him [he] PERS MASC 3S ACC @P<, [,] PU @ PU (<LE>, 1835)

In example (2), the prepositional phrase is not interpreted as an adverbial or adjunct and the noun (*copies*) is annotated as prepositional object / valency.

- (2) you [you] PERS 2S/P NOM @SUBJ> can [can] <aux> V PR @FS-<**ADVL** be [be] <aux> V INF @ICL-AUX< **furnished** [furnish] <mv> V PCP2 PAS @ICL-AUX<

Table 2. Features examined in the study and corresponding VISL tags

POS	Functional Category	Definition
MV /PRP	@[<] ADVL [>]	adjunct [free] adverbial
MV /PRP	@P<	argument of preposition
MV /PRP	@[<] PIV [>]	prepositional object / valency

with[with]PRP @ <PIV copies [copy] <cjt-head> <sem> <cc-r> <idf> <nhead> N P
NOM @P<

The starting point of the analysis was a selection of features (in grey) from the list of grammatical traits identified in past literature (Meshtrie and Bhatt 2008; Sailaja 2009; Schneider 2004, 2007, 2011; Schneider & Zipp 2013) as characteristic of IndEng (Table 3). Once annotated, tags for each selected feature could automatically be extracted from the corpus with the application of the *ConcApp* concordancer and then manually mapped to the corresponding structural patterns selected for the study (Table 3).

In order to estimate the occurrence of those patterns in British English as well, the findings were compared to sample data taken from an interactive database, namely *Phrases in English* (PIE) which provides quantitative information on recurrent phrase structures in the *British National Corpus* (BNC). The queries were ordered according to specific criteria such as minimum frequency of the searched item (e.g. $n=1$), data chunk size

(e.g. $n=1000$ which corresponds to the average number of tokens examined in DiCIE) and word forms or POS tags to match or exclude from a given query within a specified range of *n-grams* (from 1 to 3).

Figure 1 shows examples from BNC through *Phrases in English* (<http://pie.usna.edu/>) which are significantly attested in IndEng sources.

Then, the forms not attested in the BNC were searched for in the *New Oxford English Dictionary* (OED) in order to get a further matching with a valuable lexicographic source including information about the history of each entry under study. This procedure was necessary to find out possible rare as well as dated occurrences attested in BE as well as in the DiCIE. This method revealed that forms in the DiCIE such as *be fathered upon/on*, *descanted on*, *lavished upon*, *removed to* not attested in the BNC were archaisms attested in the OED. The comparative analysis was therefore carried out to test two main hypotheses:

Hypothesis 1: Data dating back to different time periods show a number of shared traits of convergence toward a set of nativized/localized forms or linguistic habits.

Hypothesis 2: Data dating back to different time periods show clear signs of divergence with respect to: (a) the target norms (BE) and (b) the set of localized forms identified in previous literature.

Table 3. List of structural features (in grey) examined in the study

Grammatical Features	Type of VISL Tags Used
Verb Phrase: -Particle verbs -Changes in valency patterns	MV PRP functionally specified as: @ADVL=adverbial; @PIV=prepositional object
Preposition Phrase: -Prepositions	MV </>
Lexico-grammar - Collocations/Phraseology	(as dependency markers)

Figure 1. Examples from BNC through phrases in English

Results

Particle Verbs

In previous descriptions of the IndEng variety, particle verbs have been pointed out as the most typical and innovative area of lexicosyntactic Indianisms (Sedlatschek 2009, p. 149). To test whether any of the early attested combinations (in 1835) had followed a gradual path toward integration and stabilization in IndEng over the years, the comparative approach of using each sub-corpus compiled for each decade side-by-side was employed to describe the development and use of those combinations.

Table 4 gives the occurrences of the individual combinations across decades in the DiCIE as well as in the British National Corpus.

Since the interpretation and selection of prepositions as arguments and/or adjuncts is a semantic class phenomenon rather than an item-specific phenomenon (see ‘Background’), the forms attested in the corpus were then grouped by both semantic domains and following particles (Table 5).

Though the individual counts for each ‘deviant’ occurrence emerging from the analysis of the data are very low to reach statistical significance, their occurrence in the corpus is a ‘linguistic event’ that cannot be disregarded, ‘since the corpus linguist is interested in assessing and interpreting the results anyway’ (Schneider & Zipp 2013).

Discussion

The study of the data attested in the DiCIE has been carried out following two types of analy-

Table 4. Occurrences of verb-particle combinations across time periods

	BNC (2011)	1835	1894	1909- 1931	1940- 1947	1951	1978	2010	N=

	<i>quibble over</i>	Communicative	1
<i>for</i>	<i>contend for</i>	Communicative	1
<i>by</i>	<i>subsist by</i>	Existence	3

sis. Following a purely data-driven procedure, the annotated corpus was first queried for the structural patterns underlying both phrasal verbs and particle verbs through their morphological features and syntactic dependencies. Then, the patterns of occurrence of the grammatical features identified in the DiCIE were compared to those attested in BE by querying the BNC. The results of previous analyses of the corpus had already shown that particular lexico-grammatical patterns are attested in DiCIE but not in ICE-IND where some other non-standard English patterns can occur (e.g. SINGH-S *India's regard and respect in our ancient culture, My respects to all at home* vs BE *respect for*) (Calabrese 2012). In some other cases (ib.), two competing constructions could co-occur within the same corpus (e.g. ICE-IND *Health permitting I would like to attend to Platinum Jubilee* along with *It was a very good*

news that you attended a meeting of the Board). The current study has shown some changes in the valency patterns of some verbs (e.g. *accept of, acquire of, approve of, lack in*) resulting in the creation of new verb-particle constructions as well. From a diachronic perspective, therefore, a remarkable difference emerges between the data from 1835, 1909, 2010 sources and the BNC as far as the occurrence of verb-particle constructions is concerned. While the texts from the year 2010 contain examples of items such as *quibble over, return +obj.+ to*, no such constructions can be found in the samples from the year 1909.

FUTURE RESEARCH DIRECTIONS

The comparison of data from different time periods suggests that, along with regular standard usage of common particle-verb combinations the creation of new combinatory lexico-grammar patterns is an overall phenomenon occurring regularly and steadily over time, even though regularity in the occurrence of individual items is attested only for a couple of items as shown in Table 4. At this stage, there is no definitively explanatory information from the available materials to establish whether the innovative elements attested in the corpus reflect an individual or an entire community of speakers' linguistic habit. Regular occurrence of innovative features in other sources across time needs to be further investigated to provide evidence of their stabilization in the variety.

CONCLUSION

The analysis of the data has shown rare signs of convergence over time. As matter of fact, some evidence of 'divergence' represented by innovations in lexico-grammatical patterns has emerged probably due to an augmented transparency. Linguists generally tend to distinguish between intralinguistic and extralinguistic factors when discussing principles underlying change and

evolution. Conditions which are purely internal to language depend on speech production, perception, and processing, whereas extralinguistic conditions include factors determined by language use in historical and sociolinguistic settings. Some of them can be explained by speakers' simplification strategies aiming to increase the economy of speech production in language contact situations which leads to the omission of inflectional endings, copulas, articles or the use of redundant form / meaning pairs. Some other forms attested only in 1909 sources far from being considered as individual or community innovations have simply become obsolete (e.g. DiCIE-LET-1909- *I crave your indulgence*) in modern English usage (see OED). Moreover, two of the most effective factors influencing any variety of English are represented by spatial distance and degree of contact with the changes that take place in the language among native speakers which will result in substantial differences across varieties. Although these findings cannot be given a highly statistical backing, they appear to reflect a general attitude on the part of IndEng speakers using such items more frequently in the years 1835, 1894, 1909 and 2010 than in the other years examined.

KEY TERMS AND DEFINITIONS

Colonial Lag: The expression used to refer to the consequent conservatism in colonial varieties as a potential factor in distinguishing them from their home counterparts in all levels of language.

Convergence: Here used to characterize phenomena specifically occurring in language contact situations which lead to changes in grammar.

Diachronic: Linguistics investigates the historical development of languages and their changes over time.

Synchronic: Linguistics describes a 'state' of a given language at one point in time.

Sociolinguistic Area: An area where shared patterns of use can be observed especially in contact situations.

Structural Nativization: Structural changes in a new variety combining features from both the substrate and the superstrate languages.

Vernacular Universals: Universally shared features across varieties of English around the world.

ENDNOTES

¹ Early Modern English covers the period when the first British settlers arrived in India; Late Modern English can be referred to the period when early attempts to introduce English in formal education were made in India (Mahmood 1895; Law 1915).

² See for example Bauer (2002, p. 9) who motivates rothicity in North America with the origin of most English-speaking settlers from rothic regions of Great Britain.

³ See Baugh & Cable 2002, 344.

⁴ A comprehensive and updated study of verb-particle constructions has been recently published by Thim (2012) who also provides an extensive review of past literature.

⁵ To effectively illustrate the process of development from the literal meaning to the figurative one, Kennedy (1920, p.15) compares, among the others, the different meanings of compound verbs such as *overlook*, *overtake*, *overturn*, *withdraw* and *withstand* with the corresponding verb-particle combinations *look over*, *take over*, *turn over*, *draw with* and *stand with*. The aspectual meaning of post-verbal particles such as *away*, *down*, *through*, *up* is interpreted as a figurative extension of the concrete meanings of the original adverbs (ibid.).

⁶ Synthetic constructions like pre-verbal incorporated adpositions can be found all over Germanic and Romance languages, in which prepositions have been incorporated

- as verb prefixes (Givón 2009, p. 109). The same process of incorporation can be said to be still going on in English in which prepositions are incorporated post-verbally in conformance with the current V(erb) O(bject) word order (ibid., p. 110).

Negotiating Local Norms in Online Communication

Jonathan R. White
Högskolan Dalarna, Sweden

INTRODUCTION

This entry deals with norms of language use in online communication. Norms are a controversial issue for language learners, in particular when it comes to English usage. There are many varieties of English around the world, but they have different statuses. It is still the case that, for many learners, British and American English have the highest status, and are the only really “proper” varieties to learn; but for others the colonial and cultural hegemony associated with them makes them irrelevant, and even inappropriate, in local contexts.

The Internet has got the reputation of being very open regarding freedom of speech (cf. the Wikileaks scandals), and for being a place where very informal, speech-like language is used. Research has shown, though, that language use online can be a way for social minorities to find a voice, and for those with lower confidence levels to communicate more. Also, it has been demonstrated that non-native speakers contribute more in discussions online, especially with native speaker interlocutors, compared to face-to-face communication. Discourse communities in general have also been argued to develop their own language practices, through the act of using language. The issue under investigation here is what norms do Internet novices adopt in online communication with native speakers of English?

Language production in online seminars by learners of English is analysed to see what norms they develop. The learners are studying on a net-based MA programme in English Linguistics. They were novice Internet users and had never

taken a net-based course before this programme. Mostly they were native speakers of Vietnamese, apart from two speakers of Bangla, both cultures which value respect for teachers. The specific norm analysed are reduced forms, where users reduce either the form or formality of linguistic expressions, for example, writing *info* instead of *information*, or *yeah* instead of *yes*. Given this background, and given that it is an education context, we might predict that their language production will be more oriented towards the norms of their native English-speaking teachers, and be more formal. In fact, this was not the case, and there was evidence that the learners clearly developed their own norms of language use. Thus, this constitutes strong support for the idea that online communities develop their own local norms through using language.

The next section presents the theoretical background to these issues.

BACKGROUND

English in the World

The status of English as a global language is a phenomenon of a modern globalised world. However, the power of English is controversial, a controversy which for many has its roots in colonialism and cultural hegemony. While English is the premier lingua franca for international communication, many see using its norms, and particularly those of British and American English, as betrayals of their cultural identity.

Kachru (1985) described the classic three concentric circles of English in the world, moving from the minority Inner Circle of native speaker norms, to the Outer Circle of the (mostly colonial) countries where English is the institutional language of government and education, etc., to the Expanding Circle of the rest of the world where English is a second or foreign language. Out of this World Englishes movement has come the strong belief that all varieties of English should have equal status, especially as targets for learners of English.

However, Expanding Circle varieties have had an equally controversial status, just as British and American English have. While some varieties have come to be viewed by the local population as acceptable varieties to learn and use, others have been derided as examples of “bad English”. However, even such well-entrenched varieties such as Singapore English are not immune to criticism. Rubdy (2001) noted that the Singapore government had launched a “good English” campaign to clean up the use of Singapore English. In countries like China, there is even stronger criticism of the local variety, demeaningly named “Chinglish”. In their surveys of attitudes of Chinese learners and teachers of English, Jin (2005) and Hu (2005) reported that speakers were very negative towards Chinglish, and for them, American English in particular was preferable. However, the situation among teachers of English is somewhat mixed. Hu (2005) noted that half of all teachers surveyed preferred to teach China English, and two thirds of them thought that it would become the standard for teaching English in China (the same has also been reported by He & Li, 2009 and Xie, 2014). The same debate is ongoing concerning Korean English or Konglish (cf. Rüdiger, 2014, for example).

An alternative view comes from the English as a Lingua Franca (ELF) movement. Given the fact that the Expanding Circle is much bigger than the rest, with roughly two-thirds of English speakers being non-native speakers (cf. the SIL Ethnologue,

www.ethnologue.org), learners should be taught explicitly how to communicate intelligibly with other learners. For instance, Jenkins (2002, 2007) has proposed a core of pronunciation features that are relevant for learners in lingua franca settings. However, this focus on communication involving non-native speakers only, plus the fact that there is still a prescribed set of norms that should be taught, has been criticised as being as extreme a position as one where native speaker varieties are seen as the only correct ones.

Canagarajah (2007: 94) refers to ELF as “a social process constantly reconstructed in sensitivity to environmental factors”; and Park & Wee (2012: 46) state ELF is “always shifting in form and situated within specific contexts”. Regarding native speakers’ place in such International Englishes, Berns (2008: 329) puts it that “native speakers have an important role, not as norm-setters, ..., but as partners with non-native speakers...”. Thus, we see it that all speakers need to adapt in cross-cultural communication settings, and it is in the interactions between speakers of English, both native and non-native, that norms of usage are negotiated. Indeed, we can even argue that the native/non-native dichotomy is obsolete, and that we should simply talk about “users of English”.

This leads us onto norms in online discourse communities.

Norms in Online Discourse Communities

As argued by Pennycook (2010) and Park and Wee (2012) for example, language is a product of social action, and embodies the social practices that brought it about. According to Pennycook’s (2010) ecological perspective, languages adapt to the environment they are used in. Language practices are negotiated and embodied in discourse communities, which are a “locally created social category” (Llamas, 2007: 581); and are “constituted by the language practices they engage in” (Pennycook, 2010: 124).

In the community of practice approach, discourse communities are seen as groups of individuals engaged in a particular task, with mutual engagement in that task, and with discourse practices to discuss that task (Lave & Wenger, 1991; Wenger, 1998). Communities set their own norms and practices internally, although there may be outside influence on them. As Canagarajah (2013: 7) puts it, "...grammatical norms ... evolve from local language practices sedimented over time" but crucially adds that "...they are always open to renegotiation and reconstruction as users engage with new communicative contexts". So, norms in communities are fluid and can be changed. Li (2010) has noted that the Internet is leading to changes in perceptions of norms in English, which is why we will focus on online communication in our analysis.

Communities of language learners are an area of special interest to us, as they very much depend on the norms they are introduced to through pedagogical materials. The choice of what norms to promote and admit in assessment is of vital importance for teachers and learners alike. We mentioned in the introduction that we will concentrate on one particular norm of online communication, reduced forms. White (2011, 2014a, 2014b, 2015b) has argued in previous work that the use of reduced forms is evidence that a community of practice is being built and sustained, as they are examples of discourse practices negotiated by that online community. Thus, our basic question here is what kinds of norms for reduced forms are negotiated in online learner communities, those of native speakers or the learners' own?

Much research in online discourse has identified reduction processes for the purpose of speeding up communication, among other functions (cf. Herring & Zelenkauskaitė, 2009). There are many different classifications of reduction processes, but we concentrate here on some very general categories. The following simplified system for reduced forms will be adopted for this analysis based on the common categories identified in the literature, as argued for in White (2015a: 76):

1. *Clippings (using pl for please, plus acronyms and initialisms).*
2. *Homophone respellings (using 4 for for).*
3. *Phonetic respellings (using yeah for yes, or evry for every).*
4. *Mixed categories of clipping plus homophone or phonetic respelling (using cos for because, or plz for please).*

The focus here is specifically on the reductions in orthography and morphology, although formality is an issue in phonetic respellings like *yeah* as well, as we see that these mark a particular type of discourse community. Other categories such as the orthographic expression of emotion and intonation, etc. are important features of CMC in textchat, but they are not of interest in this work.

Now, we present the data and participants in the study before we move on to the analysis.

NORMS IN ONLINE COMMUNITIES

Data and Participants

The participants in this study were users of English as a second language (30 in total), and were students on a net-based MA programme in English Linguistics run by a university in Sweden. They were not specially selected for a study, although they were told that the work they produced on the programme could be used by teachers for research purposes. Their consent was sought for the material to be used, informing them that they could say no at any time, and only those who gave their consent were included in the study. Two were Bangladeshi students studying in Sweden, and the rest were Vietnamese students based around Vietnam. The Vietnamese students were teachers of English at universities and colleges. All students required an average IELTS score of 7.0 to be admitted onto the programme. Their ages ranged from 23 to 45, and seven were men. An important reason why this material was used for a study was that the students were novice In-

ternet users, and so it is unlikely they will have had access to native speaker norms in English computer-mediated communication before. As mentioned in the introduction, this was also their first experience of net-based education. Thus, the way they developed their discourse community and language practices was of particular interest.

The course where the data was taken from was the first course on their programme, an introduction to core topics in English linguistics, such as phonetics, morphology, and different sociolinguistic topics run in the Autumn semester of 2007. Thus, this was their absolutely first experience of net-based education. The data comes from seminar discussions with three teachers who are users of American, British and Irish English, respectively. The discussion in the seminars took place through Skype textchat. It is important to remember that the classes were not focused on proficiency, which will affect the way language is used. All students have been made anonymous in the presentation of the data, and are referred to as, e.g. Student 15. Typographical errors have been preserved.

The data was analysed linguistically through manual analysis first of all, by identifying reduced forms and counting which students used which forms. These were then checked by using the free concordancer software, AntConc, available from http://www.antlab.sci.waseda.ac.jp/antconc_index.html.

Having presented the data and discussed issues to do with the methodology employed, we present our analysis.

How Were Norms Negotiated?

If we consider first how the students interact and negotiate norms, we see that they generally support one another when a new reduced form is used:

Extract 1

Student 28: *bb*, all you

Student 6: *take care*

Student 4: *Goodbye*

Student 13: *Bye, Teacher 1*

Student 11: *Bye. will we meet tomorrow, summer group?*

Student 6: *bye everyone*

Student 8: *bb*

[Phonology seminar, Spring and Summer groups]

We find Student 28 using the informal *bb* for *goodbye*, which is then picked up by Student 8. There are, though, many examples of students persisting in their own norms:

Extract 2

Student 27: *ex: asked me in full pronunciation is {aSk t mi}, but when we speak fast we only pronounce {as mi}*

Student 23: *yes*

Student 22: *Elision is a process that not pronouncing segment that might be present in the deliberately pronouncing of a word isolation*

Student 22: *Do you think so*

Student 25: *elision is typical of rapid, casual speech, the process of change in phoneme realisations produced by change in speed and casualness of speech*

Student 21: *can you give more examples*

Student 24: *I agree with Student 22*

Student 25: *eg: loss of weak vowels*

[Phonology seminar, Winter group]

Student 27 uses *ex* for *for example*, but Student 25 uses *eg* which is the more standard (Inner Circle) norm.

In these communities, leaders in groups have a high status. The cohorts on the programme were divided into four groups, each with a leader. This leader was responsible for keeping order in discussions, and for arranging and leading group discussions without teachers. We see that leaders particularly strongly affect the others when they use particular reduced forms. Consider the following extract:

Extract 3

Student 21: *I think so*

Student 21: *u r just going too fast*

Student 20: *I agree*

Student 14: *I think so*

Student 22: *the same to me*

Student 18: *u have to describe the position of each ending sounds and u know why*

[Phonology seminar, Autumn and Winter groups]

The leader of Winter group, Student 21, uses *u* as a reduction of *you*, and this is picked up by Student 18. However, it does happen that leaders are not followed, as the following shows:

Extract 4

Student 21: *qu3*, page 69

Student 25: *ing*

Teacher 1: *yes*

Student 25: *Q3*

[Morphology seminar, Winter group]

Here, we see Student 21 again using a reduced form, this time *qu* instead of *question*. In this case, though. Student 25 does not adopt this form, but uses *Q* instead. This non-adaptation, though, does not happen so often, and thus students are most often cooperative in adopting forms. It is also rarer, but we do also see non-leaders affecting other non-leaders:

Extract 5

Student 2: *EX pat -bat*

Student 12: *sorry I've lost which part are you discussing?*

Student 3: *how can we know that they are not overlap*

Teacher 1: *Are we all clear on how to establish if two sounds are allophones of one phoneme?*

Student 2: *I mean minimal pair*

Student 4: *complementary distribution, Student 12*

Student 9: *for ex in the words She and Shoe*

[Phonology seminar, Spring and Summer groups]

Student 2 uses *ex* for *for example*, which is then picked up by Student 9 (this form did not appear earlier in the discussion). Note that a similar form is supported in a separate group in Extract 2 above. Their groups are led by Students 1 and 7.

We have seen here, therefore, that students are generally cooperative when negotiating norms, but that individuals can persist in their own usage. High status individuals in the community in particular have power in this process. This is expected in dynamic communities where norms can be renegotiated, and it is also evidence that we have a community of practice which is in the process of negotiating its linguistic practices.

Next, we consider the role of the teachers in norm-setting.

Teachers and Norms

Given their status in Vietnamese and Bangladeshi cultures, we might expect the norms the English-speaking teachers follow would be adopted by the students. Indeed, we do find examples of this type:

Extract 6

Teacher 1: *Student 4, what exactly do you want ex of?*

Student 9: *very clear*

Student 8: *it's ok but too abstract*

Teacher 1: *Student 5? can you be specific?*

Student 8: *I mean too abstract*

Student 5: *ex of co-articulation effect*

[Phonology seminar, Spring and Summer groups]

This first extract has Teacher 1 using *ex* as a reduction of *example*, and this is adopted by Student 5. Thus, we see that native speakers do have some influence on norms in this community. However, these are rare examples, and mostly students do not adopt teachers' norms at all. The following is a representative example:

Extract 7

Teacher 1: *T.Hanh*, all sounds are allophones of some phoneme

[... three contributions missing...]

Student 18: Can 2 allophones have the same environment?

[... seven contributions missing...]

Teacher 1: Hanh, not if they are allophones of the same phoneme

Student 17: no, I mean

Student 18: Can I give an example of Vietnamese words?

Student 17: example of what?

Student 7: please go on *thuy hanh*

[Phonology seminar, Autumn and Winter groups]

Teacher 1 reduces the name of one student to *T.Hanh*, Student 18. However, Student 7 does not adopt this practice, though, but uses the full name, *Thuy Hanh*.

On the contrary, we find teachers adopting student practice, as in the following:

Extract 8

Student 15: We all have done *Q.3*

Student 17: Teacher 2, may be we should take another textbook.

Student 18: no problem with handout

Teacher 2: yes, i agree. we have one we use with other students that's much better

Student 20: that's good

Student 15: but with Research tasks

Student 14: yes

Student 15: difficult

Student 17: which one?

Teacher 2: so what did you get for *Q3*?

[Morphology seminar, Autumn group]

Teacher 2 uses the reduction *Q* for *question*, following Student 15's use.

Thus, the teachers can be seen to have limited influence on the norms negotiated by the community. Given the background of these students, namely that they were novice Internet users and

were new to net-based education, it is surprising that they still actively negotiated their own norms separately from those practiced by their teachers. We propose that it is an affordance of net-based education that they were able to do this. The community they formed were able to negotiate their own norms due to the distance created by the online environment.

Finally, we turn to how the teachers were addressed.

Addressing Teachers

When it comes to the status of teachers in this community, we see that they still do have high status. As mentioned in the introduction, teachers are held in high respect in Vietnamese and Bangladeshi society, and so should be addressed formally. We find this in the following common greetings:

Extract 9

Student 4: Thanks, *teacher*. and I am still in vague about bound morpheme, are functions only as parts of words are bound morphemes?

[Language and the media seminar, Autumn-Winter group]

Extract 10

Student 4: more examples on co-articulation effect and assimilation, *Prof Una*

[Phonology seminar, Spring and Summer groups]

Extract 11

Student 25: hOW ARE YOU, *Mrs Una*?

[Phonology seminar, Winter group]

We see a variety of formal address forms. There are plenty of reductions, though, especially of this author's name which tended to be reduced to single syllables like *John/Jon* or *Jo*, as we see in the following:

Extract 12

Student 13: *Jo online now.*

[Morphology seminar, Spring group]

As the teachers were told informally by the students, they would not be able to refer to their Vietnamese teachers in this way, and this social pressure is still apparent, in that we see students asking whether it is ok to use a particular reduced form to address a teacher:

Extract 13

Student 17: *Hello, Jon. Can we call you like that?*

[Morphology seminar, Autumn group]

Student 17 asks if it is ok to use *Jon* as an address form. In face-to-face interactions with the same teachers at a university in Hanoi, the students were much more reluctant to use similar shorter forms, and even to use the teachers' given names. Given that very different behaviour is evidenced in online discussions, we see that this is further evidence that it is an affordance of net-based education to create closer, less formal discourse communities, and to create new social environments for interaction. The same sorts of conclusions have been made for computer-mediated communication regarding the amount and quality of communication by non-native speakers in much literature (cf. Sauro, 2012; Jenks, 2014, among others).

Recommendations

We have given evidence that even novices to net-based education create their own norms through using language. These norms are negotiated by the discourse community itself, mostly not adopting the norms that their teachers practiced. This suggests that communities act independently in negotiating their own language practices. This can be argued to promote the conditions for community autonomy and will lead more readily to

learner autonomy. Therefore, we would like to propose that as teachers in academic discussion classes we should be more allowing of these practices. Such discourse environments have specific language practices, and other communities will adopt similar or completely different norms. It is up to the community itself to negotiate and adopt these practices. Through this, they strengthen the community and thereby facilitate the individual autonomy necessary for learning.

FUTURE RESEARCH DIRECTIONS

This research can be taken in a number of directions. Firstly, similar communities can be followed over a longer period of time to see if similar practices are negotiated, especially in an academic environment. Less formal communities may well negotiate in very different, and even more explicit, ways. In terms of pedagogy, an experiment can be set to compare a group that is allowed freedom to set their own language practices with one whose norms are restricted. How would the latter group react to these restrictions? A hypothesis that could be tested here is that the restricted group would prove to be less autonomous than the open group.

CONCLUSION

To conclude, we have seen that communities set their language practices independently of outside control. Groups of novices at net-based education were found to negotiate and adopt their own practices. This was argued to be strong evidence that a community had formed and was able to independently set its own practices. We hope we have convincingly demonstrated that in spite of cultural and linguistic influences, users of English can still practice and create their own language. To us, this is a sign of a strong community which allows its own norms to be negotiated and practiced.

KEY TERMS AND DEFINITIONS

Discourse Community: A group of language users who communicate on a particular topic.

Inner Circle: The highest status varieties of English consisting of the “colonist” varieties.

Lingua Franca: A language variety used for communication between non-native speakers.

Net-Based Education: Education taking place primarily through online resources.

Norm: A linguistic form agreed upon by a discourse community as appropriate in a particular situation.

Reduced Form: Linguistic expressions reduced in form or formality.

Textchat: Quasi-synchronous use of language in written form.

Architecture of an Open-Source Real-Time Distributed Cyber Physical System

Stefano Scanzio
CNR-IEIT, Italy

INTRODUCTION

Cyber physical systems (CPSs) (Guan et al., 2016) are based on a number of nodes connected through a communication network, which can interact with the environment. Application contexts that foresee the use of CPSs are Industry 4.0, building automation and smart grids (Yu & Xue, 2016). In such systems, nodes are connected through a wired or a wireless network, but commonly a typical configuration relies on the combination of both. In many applications, such as those regarding manufacturing systems, determinism on data exchanges between nodes of the system is the most important requirement.

On the other hand, in recent years, open-source software and applications are approaching CPS market. Open-source provides a low cost and effective method to implement inexpensive, performing and bug free applications. The need of open-source components for many application contexts derives from their capability to be highly customizable. This characteristic impacts directly on performance to perform actuations or sensing physical quantities, in terms of determinism and latency. The use of open-source software for real embedded systems has been described in the book (Cibrario Bertolotti, & Hu, 2015). Other examples of use of open-source software will be provided in the next sections. In the PC world, the Linux operating system is an example of widely adopted open-source platform, which offered long-term support and development. These last features are really important for systems such as CPS, which are updated and replaced infrequently. The Linux

operating system is often chosen by researchers, users and developers. Moreover, the code of the operating system, and of its software suite, is well documented, allowing to expert users a really high degree of control of any behavioral aspect. From the network point of view, Ethernet is the “de facto” standard for wired networks. Regarding wireless, a number of technologies exist, but the most common, fast and easily interoperable with Ethernet is IEEE 802.11, also known as Wi-Fi. For cost reasons and ease of configuration and installation, these technologies are the best candidates for a CPS based on open-source components. It is worth pointing out that, while the majority of protocols for industrial automation rely on Ethernet, possible candidates in industrial CPS for wireless extensions are IEEE 802.11, Bluetooth or wireless sensor networks based on the IEEE 802.15.4 standard (Lu et al., 2016).

In this chapter, a possible implementation of a CPS based on the Linux operating system is presented. The proposed architecture exploits the RTAI or XENOMAI hard real-time schedulers to guarantee the required degree of determinism of nodes. It makes use of synchronization protocols, in both the wired and the wireless extensions, to provide all the nodes a common view of time. Transmission latency can be reduced in the wired network by using hard real-time protocol stacks (such as, e.g., RTnet) and channel access methods as the time division multiple access (TDMA). Regarding Wi-Fi, redundancy techniques based on the transmission of the very same data packet on two non-overlapping networks allow to reduce both the number of packets lost and latency. Fi-

nally, we will show how the proposed architecture simplifies the integration of popular industrial protocols (e.g., EtherCAT or Modbus TCP) within the communication system.

BACKGROUND

CPSs usually interact with the surrounding environment through a wired or a wireless network. Sensing applications used to measure physical values are characterized by few timing requirements. Usually, a network wide notion of the time is maintained through specific synchronization protocols. Common time allows network nodes to associate a time to measured values. It is the case of wireless sensor networks (WSN) (Zaman, Ragab, & Abdullah, 2012) or monitoring systems. A large class of CPS applications is control systems (CSs). In CSs, remote actuators have to be continuously managed by a control unit. In its control-loop, the CS cyclically makes use of data acquired by remote sensors to properly command actuators. The main requirements of CSs are the determinism of the communication network and its reliability. In practice, a network packet has to reach the receiving node within a predefined deadline. In hard real-time (HRT) systems deadlines cannot be exceeded, while in soft real-time (SRT) systems they can be exceeded with low probability, i.e., the deadline miss ration has to be bounded. For wired networks, a number of protocols, technologies and node architectures, typically originated from the industrial world, are able to ensure HRT constraints. Nowadays, only SRT is possible for wireless networks. This is mainly due to the non-exclusive use of the communication medium (i.e., the ether) by nodes involved in the communication. Nevertheless, a number of countermeasures appeared in scientific literature to increase determinism and reliability of wireless protocols, especially for Wi-Fi. Finally, in such type of networks, nodes have to send packets with the correct timing constraints, to ensure the determinism required by the application. To this

extent, RT properties of nodes have to be improved by using, e.g., a RT operating system. In the following, design guidelines and references will be provided for the implementation of a distributed wired/wireless CPS, with completely open-source components, RT capabilities and conventional hardware.

OPEN-SOURCE ARCHITECTURE FOR A REAL-TIME CPS

Architecture

A reference network architecture of a CPS is schematically presented in Figure 1. A *wired backbone* interconnects *wired nodes*. In the proposed open-source architecture, it consists in standard Ethernet cables and switches. Some *wireless extensions* are connected to the wired backbone. They allow node mobility and cable replacement for such applications in which cabling is hard or cables are prone to wear and tear (e.g., in robotic arms). Wi-Fi has been chosen as the reference wireless technology for wireless extensions because it is faster if compared with other WSNs technologies, it is completely interoperable at the data link layer with Ethernet, and its basic components (i.e., access points (APs) and Wi-Fi adapters) are available off-the-shelf at relatively low cost. APs are used as interconnection elements between the wired backbone and wireless extensions. Two types of Wi-Fi nodes can coexist in the same CPS: conventional *Wi-Fi nodes* and redundant *Red. Wi-Fi nodes* equipped with two or more wireless adapters. The latter type of node is used for SRT applications with demanding latency and reliability requirements. Some nodes can be equipped with both wired and wireless adapters. An example is the border node of a *Wi-Fi subsystem* (e.g., the interface node of an industrial machinery produced by a specific vendor) which is connected to the wired backbone to communicate with other components of the CPS and internally exploits wireless communication for the connec-

Figure 1. Reference architecture of a CPS

tion with moving elements. Finally, some specific network segments may require a high degree of determinism. In this case, *specific HRT network protocols* can ensure the expected performance. Both wired and wireless nodes of the CPS are personal computers (PCs) or embedded systems running the Linux operating system.

Wired Backbone

In the proposed architecture, wired backbone is based on the IEEE 802.3 Ethernet standard. Switches are used to interconnect wired nodes. As a matter of fact, the level of determinism in terms of latency of switched Ethernet is enough for the majority of the CPS application contexts. Nevertheless, switches introduce indeterminism on delivery time, because packets queued inside them experience a delay that depends on network traffic. To avoid this problem, a synchronization protocol can be used to provide a common notion of time to nodes. As a consequence, if network packets containing a command arrive to the receivers sufficiently in advance, synchronized actuations can be performed by different nodes,

even if the underlying communication network is not deterministic enough. Synchronization protocols will be analyzed in detail later. If the network packet containing the actuation command cannot be sent sufficiently in advance, because the actuation command is based on other sensors data that must be adequately new, network determinism has to be improved. A common and effective remedy is traffic prioritization. Most important traffic has to be tagged with the higher priority, as define in IEEE P802.1p standard, to increase Quality of Service (QoS). Such solution is adopted by the EtherNet/IP industrial protocol. Further advantages can be achieved by using specifically modified switches. For example, in TTEthernet high priority traffic is sent on specific time intervals. TTEthernet ensures that in such intervals other traffic cannot interfere with the high priority one. TTEthernet preserves the compatibility with standard Ethernet (i.e., traffic is routed with conventional Ethernet rules outside the reserved intervals). Unfortunately, as other HRT protocols, TTEthernet requires specific and expensive hardware. A software-based, less expensive and less deterministic solution, is TDMA. In TDMA,

synchronized nodes subdivide the communication network in time slots. Each node is then allowed to transmit only in its assigned slots, preventing possible interference with other network nodes. The main disadvantage of this technique is that all nodes have to implement TDMA.

Quite counter-intuitively, in relatively small networks, the major source of indeterminism is not the network, but is the node itself. A simplified schema of a Linux-based PC is reported in Figure 2.

In a PC, concurrently, a number of processes make use of the central processing unit (CPU). Between these processes, the control application (CA) is in charge to manage the transmission and reception of the relevant data of the CPS. The transmission of a packet (e.g., to perform an actuation on a remote node) by means of the CA is usually triggered by a timer or by the reception of another packet, which for instance contains a new sensed datum. In both cases, when the CPU is in use by others process, a context switch operation to substitute the running process with that of the CA is needed. The additional delay to save the context of the old process and to restore the CA context worsen the HRT capability of the node, if compared with the more favorable case

in which the CPU is idle when the CA process is triggered. To send the packet, the CA that runs in user-space makes use of the *system calls* provided by the operating system. System calls software is executed in kernel-space. The transition from user to kernel spaces requires another context switch operation, which leads to further indeterminism. Moreover, the use of shared resources by means of concurrent processes decreases determinism (e.g., the access to the Ethernet adapter or to the main memory is performed through the shared system bus). Additionally, the reaction time of the system to an interrupt depends on pending interrupts not yet managed by the CPU. A first remedy is the installation of specific Linux kernel patches with the aim to reduce the time intervals in which the operating system cannot be preempted by other ready processes, such as the CA. The most known is RT patch. Among its most important features, it minimizes the time in which the CPU is not sensible to interrupts and it allows the Linux kernel to assign a priority to each interrupt (i.e., a major priority can be assigned to Ethernet adapter and timing interrupts). Although RT patch allows to increase determinism, the resulting system can only be considered SRT. A more effective countermeasure relies on the use of HRT extensions, such as RTAI or XENOMAI. Normal processes and the operating system itself are scheduled by these extensions as non-real-time processes. HRT processes are not scheduled by the Linux kernel but by RTAI or XENOMAI. In this way, they do not suffer of the interference caused by other non-real-time processes. Unfortunately, to guarantee HRT performance, CA software cannot make use of system calls, and device drivers have to be programmed exploiting specific RTAI or XENOMAI libraries.

The most recent article of performance comparison between standard Linux kernel, RT patch and RTAI is (Cereia, Cibrario Bertolotti, & Scanzio, 2011). Some results of that work are reported in Table 1. It analyzes the jitter (i.e., the deviation from the desired actuation time) in a system without additional load and with an inten-

Figure 2. Simplified schema of a PC wired node

Table 1. Comparison between standard Linux kernel, RT patch and RTAI

	Jitter (μ s)			
	No Load		I/O Load	
	σ	Max	σ	Max
Std. Linux kernel	5.72	1434.0	5.75	1151.0
RT patch	0.12	1.8	0.63	10.4
RTAI	0.12	2.5	0.32	8.0

Data source: (Cereia, Cibrario Bertolotti, & Scanzio, 2011).

sive I/O load of 500 IRQs per second. In the latter configuration, results confirm the impossibility to use a standard Linux kernel in RT applications (maximum jitter is 1151 μ s), and the effectiveness of RT patch and RTAI (maximum jitter is 10.4 and 8.0 μ s, respectively).

When packets have to be sent timely, also driver and protocol stack implementations must have RT properties. A commonly used HRT protocol stack for wired adapters is RTnet, which ensures a bounded delay on packets delivery. Jitters of standard Linux and RTnet were analyzed in (Cena, Scanzio, Valenzano, & Zunino, 2011). As reported in Table 2, the maximum jitter of the standard driver in the I/O load condition is for many application contexts too high (1910.6 μ s). On the other side, with RTnet, jitter remains bounded to 38 μ s.

Wi-Fi Extensions

Wi-Fi extensions are really useful in many application contexts. Unfortunately, they cannot guarantee the determinism of cables. In particular, the number and type of wireless nodes in proximity of the CPS is usually out of the control of the application designer. Choosing the band and the transmission channel of the Wi-Fi system in a frequency not exploited by other wireless networks is the first best practice. Sometimes this solution is not possible, because in a specific environment users have not control over the surrounding networks. With the widespread diffusion of mobile devices, the elimination of these interfering nodes is becoming

Table 2. Comparison between standard and RTnet protocol stack

	Jitter (μ s)			
	No Load		I/O Load	
	σ	Max	σ	Max
Standard	11.2	72.3	35.2	1910.6
RTnet	6.0	38.0	4.0	33.6

Data source: (Cena, Scanzio, Valenzano, & Zunino, 2011).

even more complicated. Moreover, electromagnetic disturbances are another source of packets loss. TDMA techniques have been extensively exploited in Wi-Fi to prevent the indeterminism of the CSMA/CA method used by nodes to manage channel access (Sevani, Raman, & Joshi, 2014). As for the wired case, synchronized nodes are allowed to transmit only in their assigned slots. Unfortunately, even with TDMA, sensitivity to channel disturbances is equal to normal Wi-Fi. In addition, to obtain a sufficient degree of determinism, these methods require that all the wireless nodes follow TDMA rules. Even if TDMA and the other listed techniques can noticeably improve channel quality, they cannot deal with protracted disturbances or heavy interferences.

An effective solution is seamless redundancy, which is based on frequency diversity. The architecture of a *Red. Wi-Fi node* implementing seamless redundancy and based on a PC is reported in Figure 3. The most significant difference with a typical Wi-Fi node is the presence of two (or more) Wi-Fi adapters.

With seamless redundancy, two copies of the same message are transmitted on distinct wireless channels. The receiver node takes care of discarding duplicates, and it forwards to the application layer only the first message copy arrived to destination. The probability that a disturbance or an interference affects all the channels involved in the parallel transmission is relatively small. Seamless redundancy for Wi-Fi was firstly proposed by (Rentschler & Laukemann, 2012) and it was based on the Parallel Redundancy Protocol (PRP), which is a protocol aimed at ensuring end-to-end

Figure 3. Simplified schema of a PC-based Red Wi-Fi node

redundancy for wired Ethernet networks. Its first adaptation to Wi-Fi relied on specific devices named RedBoxes that implement the standard PRP protocol over Ethernet. Wi-Fi equipment was connected to RedBoxes to analyze PRP performance in a wireless network. Seamless redundancy based on PRP is an end-to-end solution, i.e., between sender and receiver nodes. In Wi-Red technique (Cena, Scanzio, Valenzano, & Zunino, 2014), seamless redundancy was applied at the link level. For instance, in the communication path between two Wi-Fi nodes, the first link is between the node and the AP, while the second

is between the AP and the second node. With Wi-Red, further improvements are possible: by implementing specific techniques to avoid the sending of packets already arrived through other channels, or by exploiting heuristics for scheduling the traffic on the two interfaces.

Results published in scientific literature (Cena, Scanzio, & Valenzano, 2016) confirm that significant improvements can be achieved in real installations in terms of packet losses and transmission latencies. Table 3 compares performances of two single channels with those obtained with seamless redundancy. Results, obtained sending periodically (every 100 ms) unicast and multicast traffic, are in terms of average latency, maximum latency and percent of packet lost much better than those of the single channel. Even if, at present, a HRT driver implementation similar to RTnet for Wi-Fi adapters is not available, the use of HRT extensions such as RTAI or XENOMAI is recommend to improve determinism as much as possible.

Clock Synchronization

Synchronization makes possible the implementation of TDMA and offers some essential services at the application level. To permit the comparison between values sensed by different nodes, sensed data must be associated with a temporal information. In addition, synchronization enables different nodes to perform simultaneous actuations, addressing the indeterminism of the communication network by sending packets in advance. Synchronization protocols are based on

Table 3. Comparison between Wi-Fi transmissions on individual channels and on redundant channels

	Unicast			Multicast		
	μ	Max	Perc. Lost	μ	Max	Perc. Lost
	(ms)	(ms)	(%)	(ms)	(ms)	(%)
Channel A	0.92	100.77	0.0	1.57	106.30	0.51
Channel B	0.95	100.92	0.0	2.16	92.71	1.11
Channel A+B	0.71	8.93	0.0	1.12	44.35	0.02

Data source: (Cena, Scanzio, & Valenzano, 2016).

the exchange of specific sequences of packets, and on timestamps obtained on sending and/or reception of a subset of these packets. Timestamps are used by synchronization protocols for the regulation of nodes time by means of specific clock regulation algorithms (Mongelli & Scanzio, 2016). Their precision is directly related to timestamps accuracy. If hardware timestamping is not supported by the adapter, timestamps are typically acquired at the first instruction of the Interrupt Service Routine (ISR), executed to serve the interrupt raised by the network adapter, which follows the reception of a packet. Synchronization quality in the case of software timestamps is in the order of tens microseconds, while for hardware timestamps a typical accuracy is in the order of some nanoseconds. For wired networks, the “de facto” standard is the master-slave IEEE 1588 protocol (Cena, Cibrario Bertolotti, Scanzio, Valenzano, & Zunino, 2013). The IEEE 1588 protocol is based on a tree synchronization hierarchy, where a number of slave nodes synchronize with a master node. A slave node can act as a master for its sub-tree. For Wi-Fi, specific synchronization protocols, namely the *timing measurement* and *timing advertisement*, have been included in the 2012 version of IEEE 802.11 standard, but at the time of writing they are not implemented in most of the available off-the-shelf Wi-Fi adapters, and they have some disadvantages (Cena, Scanzio, Valenzano, & Zunino, 2015). The porting of IEEE 1588 to Wi-Fi has been analyzed in (Mahmood, Exel, & Sauter, 2014). The AP acts as a slave for the wired backbone and as a master for the Wi-Fi extension. This solution is really effective, and, above all, it makes possible the sharing of the same synchronization protocol to all the nodes of the CPS. Unfortunately, implementation requires modifications to the AP. The Reference Broadcast Infrastructure Synchronization (RBIS) protocol (Cena et al., 2015) does not require any modification to Wi-Fi equipment. As a consequence, it can be directly implemented in software on conventional hardware. RBIS requires a Wi-Fi node as

a master, i.e., the master is not the AP. This last requirement limits the possible network topologies. In fact, the master node, to synchronize with the wired backbone, has two network adapters: a wired interface connected to the backbone and a Wi-Fi interface connected to the AP. On the other side, RBIS enables the connection of Wi-Fi subsystems to the wired backbone, as represented in Figure 1. Synchronization error achieved by RBIS on a real implementation based on a conventional PC is less than 3.3 μ s (Cena et al., 2015).

Other RT Protocols

Usually, actuations and sensing have to be performed within a given deadline. To this extent, some network segments can rely on specific and more deterministic protocols, especially if the CPS is used for CSs with safety requirements. A number of HRT protocols exist, each with its own peculiarities. EtherCAT (Scanzio, 2012) is an example of really high deterministic protocol. In EtherCAT, master node can be implemented on a conventional PC. This feature and the availability of open-source software make it particularly suitable to be used in Linux-based CPS. Slave nodes, those performing sensing and actuations, are implemented in hardware to increase determinism. EtherCAT has its own synchronization protocol that guarantees a synchronization quality smaller than 50 ns (Cena, Cibrario Bertolotti, Scanzio, Valenzano, & Zunino, 2012), and which can be easily integrated with IEEE 1588 through specific EtherCAT slave devices. The most powerful open-source EtherCAT master software for Linux is EtherLab. A description of EtherLab and some guidelines for its use and configuration can be found in (Scanzio, 2012), while its performance was evaluated in (Cereia et al., 2011). An EtherCAT master implemented on a Linux-based conventional PC requires a very high determinism on sending Ethernet frames. For this reason, the use of HRT extensions as RTAI or XENOMAI is highly recommended.

SOLUTIONS AND RECOMMENDATIONS

A completely open-source architecture for CPS based on Linux, off-the-shelf network devices and standard PCs has been proposed. Determinism of nodes is achieved with HRT extensions (i.e., RTAI or XENOMAI) or with a SRT patch named RT patch. Moreover, specific HRT protocol stacks, such those provided by RTnet, can be used for wired connections. Depending on the application requirements, the proposed architecture has different levels of capability and scalability. For wired networks, it may rely on conventional Ethernet, but TDMA techniques can be used to increase determinism. Specific HRT protocols such EtherCAT can be exploited to further increase determinism. Regarding wireless extensions, if conventional Wi-Fi is not enough, TDMA is a first improvement, which can be further enhanced with techniques based on seamless redundancy. However, to the current state-of-the-art, Wi-Fi can be considered only for SRT systems, in which deadlines can be exceeded with low probability (Cena, Scanzio, & Valenzano, 2016). Finally, a synchronization service is transparently available in all nodes of the CPS. It is based on the IEEE 1588 standard for wired segments, and on recent researches for Wi-Fi extensions.

FUTURE RESEARCH DIRECTIONS

For many years, a constant research activity was targeted to improve determinism of wired networks. Its outcomes were a suite of HRT protocols that rely on Ethernet, and deterministic software and operating systems for nodes. Many of these software (and hardware) are commercial products, some are open-source, which are the most used in research. Nowadays, research activity on CPS wired networks is aimed to increase performance and to seamlessly integrate all network components (Bangemann, Riedl, Thron, & Diedrich, 2016). Regarding determinism, HRT extensions installed

on PCs have counter-intuitively worst performance than in the past, because today's CPUs are multi-core and their target is to maximize throughput instead of determinism. The evolution of the hardware requires the implementation of new algorithms and software. The use of big-data analysis and machine learning techniques is a way to improve the quality of some services, such as for synchronization protocols. Nodes virtualization allows to decrease configuration and management effort in large CPS, and it is a very promising research area, which opens many interesting investigation aspects regarding especially determinism. An even more promising research area concerns wireless. CPS has a really high demand of deterministic communication over the ether. Seamless redundancy is a new remedy, but not a definitive solution. Very large improvements can be achieved on existing techniques, and the opportunity to propose new effective methods is very high. A really heterogeneous set of wireless technologies is currently available in the market, with very orthogonal characteristics (e.g., IEEE 802.11, Bluetooth, IEEE 802.15.4, WirelessHART, LoRa, etc.). For each of these technologies, techniques to increase determinism and reliability have to be specifically implemented to obtain the maximum improvement (Lu et al., 2016). Finally, other services such localization need to be improved and included in wireless networks of the future, in order to better support node mobility.

CONCLUSION

The proposed architecture for the implementation of a CPS is based on open-source software, on standard hardware and on the Linux operating system. Other architectural solutions are possible, especially if commercial products are considered. The latter are typically easier to install and configure, but their integration in the overall architecture is more complex. The proposed open-source solution is very scalable and customizable,

especially because software components are easily modifiable and highly configurable (i.e., source code is open). The reference wireless technology for wireless extensions discussed in this chapter is Wi-Fi. It offers a number of advantages in terms of both integration with Ethernet networks and throughput. Nowadays, general purpose systems (e.g., PC equipped with Linux) and off-the-shelf devices (e.g., Ethernet and Wi-Fi adapters, or APs and switches) can be the basic components of high performing CPS. This is a great achievement. Moreover, future research activities are very promising and aimed to replace cable with wireless technology for an increasing number of applications.

KEY TERMS AND DEFINITIONS

Cyber Physical System: A system that integrates computer and networking to control a physical process.

IEEE 802.11 (Wi-Fi): A standard for the implementation of high-throughput wireless local area networks.

IEEE 802.3 (Ethernet): A collection of standards for the definition of Ethernet. Ethernet is the most known wired network technology.

Real-Time Networks: Communication networks with demanding requirements in terms of latency and determinism.

Seamless Redundancy: Inclusion of duplicate components, not strictly necessary, to improve reliability.

Synchronization Protocols: Network protocols for the distribution of a common time reference to the nodes of a communication network.

Time Division Multiple Access (TDMA): A channel access method to manage a mutual exclusive access of transmitting nodes to a network.

Wi-Red: A seamless redundancy technique applied to Wi-Fi to improve determinism and reliability of IEEE 802.11 wireless networks.

C

Consistency Is Not Enough in Byzantine Fault Tolerance

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

In Byzantine fault tolerance (BFT), a core concern is to ensure the consistency of replicas despite malicious attacks from the clients and compromised replicas (Zhao, 2014). This is accomplished by totally ordering incoming requests and by rendering the replica's operations deterministic (Zhang et al., 2011). In the presence of application non-determinism, such as the access of local clocks, replicas are rendered deterministic by forcing all non-faulty replicas to use the same values either supplied by the primary or computed deterministically. While this approach works well for some applications, such as a replicated file system, doing so could lead to the compromise of the service integrity for applications that rely on the use of random numbers.

For example, consider an Internet application that relies on the use of session-ids for stateful interactions between the server and its clients. As pointed out in (Dorrendorf, Gutterman, & Pinkas, 2007), if the session-id of an active session can be predicted, the client's session with the server could be hijacked, which could lead to the leak of confidential information regarding the client, such as name, address, and the order history, or unauthorized orders (if the one-click option for placing orders is enabled). The session-id may be predicted by searching the limited entropy space if weak random bits are used in an application. For example, the authors of (Dorrendorf, Gutterman, & Pinkas, 2007) reverse-engineered a version of Tomcat (a popular Java Servlet Engine) and the related operations in a Window's based Java Virtual Machine. They could attack the system

by performing about 251 searches in finding an active session-id.

Therefore, it is critical not to weaken the strength of the random bits essential for the integrity of their operations when replicating these systems for Byzantine fault tolerance. For a sound coordination algorithm, it is essential to enable each replica to access its own entropy source and maintain its independence in such operations. However, this desire is in conflict with the basic requirement for state machine replication (Schneider, 1990), which mandates that the replicas must be deterministic or rendered deterministic to maintain strong replica consistency. The conflicting requirements for security and replication must be reconciled to avoid the dilemma of either favoring security over high availability by not performing state machine replication of the systems, or trading security for high availability by removing the randomness of the systems in order to perform state machine replication.

In this chapter, we present a novel replica coordination algorithm, referred to as the Collective-Determination BFT algorithm, or CD-BFT algorithm in short, towards the reconciliation of the conflicting requirements for security and for strongly consistent replication. The central idea behind this algorithm is that all random numbers to be used by the replicas are collectively determined, and furthermore, the determination is based on the contributions made by a quorum of replicas, at least one of which is correct.

In the CD-BFT algorithm, the replicas first reach a Byzantine agreement on the set of contributions from replicas, and then apply a deterministic algorithm, such as the bitwise exclusive-or

operation (Young & Yung, 2004), to compute the final random value. The freshness of the random numbers generated is application dependent. Our approach does not alter the freshness of the random numbers. If a pseudo-random number generator is used, it should be periodically reseeded from a good entropy source.

BACKGROUND

An arbitrary fault is often referred to as a Byzantine fault. The term was introduced in (Lamport, Shostak, & Pease, 1982) to highlight a specific faulty behavior that a Byzantine faulty process may disseminate conflicting information to other processes. For example, a compromised process might exhibit such Byzantine faulty behavior. Byzantine fault tolerance refers to the capability of tolerating Byzantine faults in a system. It can be achieved by introducing sufficient redundancy into the system and by using a sophisticated replica coordination algorithm that can cope with Byzantine faulty replicas and clients. A basic requirement for such an algorithm is to ensure that all server replicas agree on the total ordering of the requests received despite the existence of Byzantine faulty replicas and clients. Such an agreement is often referred to as Byzantine agreement (Lamport, Shostak, & Pease, 1982).

Recently, a number of efficient BFT algorithms (Castro & Liskov, 2002; Kotla et al., 2007; Yin et al., 2003) have been proposed. Our CD-BFT algorithm is derived from the PBFT algorithm and we use the same system model as that in (Castro & Liskov, 2002). The PBFT algorithm operates in an asynchronous distributed environment. The safety property of the algorithm, *i.e.*, all correct replicas agree on the total ordering of requests, is ensured without any assumption of synchrony. However, for the algorithm to make progress towards a Byzantine agreement (*i.e.*, liveness), certain synchrony is needed, for example, a reasonable assumption is that the message transmission and processing delay has an asymptotic upper bound. This bound

is dynamically explored in the algorithm in that each time a view change occurs, the timeout for the new view is doubled.

How to ensure strong replica consistency in the presence of replica non-determinism has been of research interest for a long time (Castro & Liskov, 2002; Castro, Rodrigues, & Liskov, 2003; Powell, 1991; Slember & Narasimhan, 2006), most of which are for fault tolerant systems using the benign fault model. However, while the importance of the use of good random numbers has long been recognized in building secure systems (Viega & McGraw, 2002), we have yet to see substantial research work on how to preserve the randomized operations necessary to ensure the system integrity in a fault tolerant system. For the type of systems where the use of random numbers is crucial to their service integrity, the benign fault model is obviously inadequate and the Byzantine fault model must be employed if fault tolerance is required.

Some form of replica non-determinism, in particular those related to timestamp operations, has been studied in the context Byzantine fault tolerant systems (Castro & Liskov, 2002; Castro, Rodrigues, & Liskov, 2003). However, as we will argue in the next section, the existing approach is vulnerable to the presence of colluding Byzantine faulty replicas and clients. We also studied the replica non-determinism issue with the emphasis of classification of non-determinism types and the systematic handling of various types of replica non-determinism (Zhang et al., 2011).

RECONCILIATION OF SECURITY AND REPLICATION REQUIREMENTS

Pitfalls in Controlling Replica Randomness

In this section, we analyze a few well-known approaches that one may attempt to use to ensure replica consistency in the presence of replica randomness. We show that they are not robust

against Byzantine faulty replicas and clients. We reiterate here the importance of using random bits for security-related operations. Any attempt to weaken or remove such randomness from the system for the purpose of replication may compromise the system integrity. Furthermore, for Byzantine fault tolerance, it is essential *not* to place undue trust to any single replica, such as the primary replica, because it is virtually impossible to verify in real-time if the random number proposed by a replica is truly random, and consequently, if that particular replica is compromised, the integrity of the entire replicated system will be lost.

For systems that use a pseudo-random number generator, the replica consistency can be easily achieved by using the same seed value to initialize the generator. One might attempt to use the sequence number assigned to the request as the seed. Even though this approach is perhaps the simplest way to render replicas deterministic (since no extra communication step is needed and no extra information is to be included in the control messages for total ordering of requests), it takes the randomness away from the system. Consequently, a Byzantine faulty client can easily guess the seed and predict the random numbers. A seemingly more robust approach is to use the timestamp as the seed to the pseudo-random number generator. As shown in (Viega & McGraw, 2002; Young & Yung, 2004), the use of timestamp does not offer more robustness to the system because it a Byzantine faulty client can easily guess the seed.

The only option remaining seems to be the use of a truly random number to seed a strong pseudo-random number generator (or to obtain random numbers entirely from a high entropy source). We note that the elegant mechanism described in (Castro & Liskov, 2002) cannot be used in this case because backups have no means to verify whether the number proposed by the primary is taken from a strong random number generator seeded periodically using a high-entropy source, or is generated according to a deterministic algorithm. If the latter is the case, the Byzantine faulty primary could continue colluding with Byzantine faulty clients

without being detected. A slight improvement over this scheme is to proactively rotate the primary. However, this improved scheme does not solve the problem: while the faulty replica serves as the primary, it can use a predictable seed and/or a weak random number generator without being detected, and hence, the system integrity cannot be guaranteed during this period.

Therefore, the most effective way in countering such threats seems to collectively determine the random numbers, based on the contributions from a quorum of replicas so that Byzantine faulty replicas cannot influence the final outcome.

The Collective-Determination BFT Algorithm

The normal operation of the CD-BFT algorithm is illustrated in Figure 1. The algorithm is executed by a set of $3f + 1$ replicas to tolerate up to f Byzantine faulty replicas. One of the replicas is designated as the primary while the remaining replicas are backups. Each replica is assigned a unique id i , where i varies from 0 to $3f$. For view v , the replica whose id i satisfies $i = v \bmod (3f + 1)$ would serve as the primary. The view starts from 0. For each view change, the view number is increased by one and a new primary is selected.

All messages exchanged among the replicas, and those between the replicas and the clients are protected by an authenticator (Castro & Liskov, 2002) (for multicast messages), or by a message authentication code (MAC) (for point-to-point communications). An authenticator is formed by a number of MACs, one for each target of the multicast. We assume that the replicas and the clients each has a public/private key pair, and the public keys are known to everyone. These keys are used to generate symmetric keys needed to produce/verify authenticators and MACs. To ensure freshness, the symmetric keys are periodically refreshed by the mechanism described in (Castro & Liskov, 2002). We assume that the adversaries have limited computing power so that they cannot break the security mechanisms described above.

A compromised replica may replace a high entropy source to which it uses to seed its random number generator with a deterministic algorithm, and convey such an algorithm and the random numbers collectively determined via a covert channel to its colluding clients. We assume that a faulty replica cannot explicitly piggyback such information with a reply through the normal communication channel, which could be ensured by using an application-level gateway, or a privacy firewall as described by Yin et al. (2003). However, we assume that the bandwidth of the covert channel is very limited such that a faulty replica

cannot transmit confidential state information to its colluding clients *in real time*, more specifically, given the size of the secret data L , the refresh period T , and the covert channel bandwidth R , we assume $T < LR$. For example, if the random number is of size 32 bits, and the covert channel bandwidth is 0.1 bit/second, the refresh period should be made less than 320 seconds. How to limit the bandwidth of covert channels is still under intense research (Gianvecchio & Wang, 2007; Shah, Molina, & Blaze, 2006), and it is out of the scope of this chapter.

Figure 1. Normal operation of the CD-BFT algorithm

When ordering a request, the primary determines the order of the request (*i.e.*, assigns the next sequence number to the request), and queries the application for the type of operation associated with the request. If the operation involves with a random number as input, the primary activates the mechanism for the CD-BFT algorithm. The primary then obtains its share of random number by extracting from its own entropy source, and piggybacks the share with the PRE-PREPARE message multicast to all backups. The pre-prepare message has the form $\langle \text{PRE-PREPARE}, v, n, d, R_p \rangle_{\alpha_p}$, where v is the view number, n is the sequence number assigned to the request, d is the digest of the request, R_p is the random number generated by the primary, and α_p is the authenticator for the message.

When a backup receives a PRE-PREPARE message, it performs the usual procedure such as the verification of the authenticator before it accepts the message. It also checks if the request will indeed trigger a randomized operation, to prevent a faulty primary from putting unnecessary loads on correct replicas (which might lead to a denial of service attack). If the PRE-PREPARE message is acceptable, the replica creates a PRE-PREPARE certificate for storing the relevant information, generates a share of random number from its entropy source, and multicasts to all replicas a PP-UPDATE message, in the form $\langle \text{PP-UPDATE}, v, n, i, R_i, d \rangle_{\alpha_i}$, where i is the sending replica identifier, R_i is the random number share from replica i .

When the primary has collected $2f$ PP-UPDATE messages, it combines the random numbers received according to a deterministic algorithm in the entropy combination step, as shown in Figure 1, and builds a PP-UPDATE message with slightly different content than those sent by backups. In the PP-UPDATE message sent by the primary, the R_i component is replaced by a set of $2f + 1$ tuples containing the random numbers contributed by replicas (including its own share), S . Each tuple

in the set S has the form $\langle R, i \rangle$. The replica R_i identifier is included in the tuple to ease the verification of the set at backups.

On receiving a PP-UPDATE message, a backup accepts the message and stores the message in its data structure provided that the message has a correct authenticator, it is in view v and it has accepted a PRE-PREPARE message to order the request with the digest d and sequence number n . A backup proceeds to the entropy combination step provided that it has accepted a PP-UPDATE message from the primary and $2f$ PP-UPDATE messages sent by the replicas referenced in the set S . The backup requests a retransmission from the primary for any missing PP-UPDATE message.

When it finishes the entropy combination, a backup multicasts a prepare message. The message has the form $\langle \text{PREPARE}, v, n, i, d' \rangle_{\alpha_i}$, where d' is the digest of the request concatenated by the combined random number. The replica then waits for $2f$ valid PREPARE messages from different replicas (possibly including the message sent or would have been sent by itself), after which, it multicasts a commit message to all replicas in the form $\langle \text{COMMIT}, v, n, i, d' \rangle_{\alpha_i}$. When a replica receives $2f+1$ valid COMMIT messages, it decides on the sequence number and the collectively determined random number. At the time of delivery to the application, both the request and the random number are passed to the application.

In Figure 1, the duration of the entropy extraction and combination steps have been intentionally exaggerated for clarify. In practice, the entropy combination can be achieved by applying a bit-wise exclusive-or operation on the set of random numbers collected, which is very fast. The cost of entropy extraction depends on the scheme used. Some schemes, such as the TrueRand method (Lacy et al., 1993), allow very fast entropy extraction. TrueRand works by gathering the underlying randomness from a computer by measuring the drift between the system clock and the interrupts-generation rate on the processor.

DISCUSSION

For clarity, when describing the CD-BFT algorithm, we have assumed that each remote method invocation involves only a single random number. In practice, an invocation might need to access a number of random numbers. Our algorithm can be trivially modified to accommodate this need. Let n be the number of random numbers needed for an operation. In the CD-BFT algorithm, during the pre-prepare phase, each replica obtains n random numbers from its entropy source and includes them in the PRE-PREPARE and PP-UPDATE messages. The entropy combination step would now combine n random numbers instead of 1. The remaining steps are identical to those in the original algorithm.

If the entropy consumption rate exceeds the entropy generation rate of the entropy source, which is the case for many practical systems, a pseudo-random number generator is normally used. If such systems are replicated for Byzantine fault tolerance, unless the pseudo-random number generator is frequently reseeded, it is not wise to collectively determine the seed to the random number generator so that the sequence of pseudo-random numbers can be generated deterministically without replica coordination. This is because if a compromised replica leaks the collectively-determined seed to some faulty clients (an adversary can take the time to leak the seed number through a very low-bandwidth covert channel, if the reseeding is not carried out frequently), they can predict all the future random numbers produced by the generator, which would compromise the integrity of the system (*i.e.*, the backward security will be lost). For better security, the replicas should instead seed their pseudo-random number generators independently and collectively determine *every* random number generated. It is also advised that each replica uses a different (strong) pseudo-random number generator for enhanced security. In fact, even if all correct replicas use the same relatively weak random number generator that can be broken by

searching 2^E space, our algorithm can expand the search space significantly to $2^{(f+1)E}$ because the collectively determined random number is based on contributions from at least $f + 1$ correct replicas.

FUTURE RESEARCH DIRECTIONS

It would be interesting to do a comparison study of our approach and the threshold cryptography (Desmedt, 1994; Rabin, 1998; Shoup, 2000). Threshold cryptography can be readily used to perform many secure operations across several replicas without ever exposing the security key, and hence, it is more robust against malicious attacks because it works even in the presence of high-bandwidth covert channels between a compromised replica and its colluding clients. However, threshold cryptograph is not without its limitations shown below. How to overcome these limitations would be very interesting research topics.

- Threshold cryptograph is extremely computationally expensive. We have experimented with a Java-based threshold cryptography framework on our test-bed. For a 1024 bit-long key, the key shares generation operation takes over 1 second, and the key shares combination operation takes over 2 seconds. This might be too expensive for most Web-based applications, which require soft real-time responses. It is worthwhile to investigate if a shorter key is sufficient depending on the security requirement of an application.
- To achieve proactive threshold cryptography, the key shares must be frequently refreshed, which involves not only expensive computations, but substantial message exchanges among the replicas as well. How this step impacts the overall system performance should be evaluated.
- Threshold cryptography assumes the availability of a trusted dealer to distribute the

initial shares. How to implement such a trusted dealer would be an interesting research challenge.

Nevertheless, threshold cryptography has been integrated into some Byzantine fault tolerance systems, such as in Byzantine fault tolerant distributed hash tables (Young et al., 2009), and Byzantine fault tolerant distributed storage (Cachin and Tessaro, 2005).

CONCLUSION

The use of good random numbers is crucial to the security of many mission-critical systems. However, when such systems are replicated for Byzantine fault tolerance, a serious issue arises, i.e., how do we preserve the integrity of the systems while ensuring strong replica consistency? Despite the fact that there exists a large body of work on how to render replicas deterministic under the benign fault model, the solutions regarding the random number control are often overly simplistic without regard to the security requirement, and hence, they are not suitable for practical Byzantine fault tolerance. In this chapter, we have presented a novel integrity-preserving replica coordination algorithm for Byzantine fault tolerant systems. The central idea behind our CD-BFT algorithm is that all random numbers to be used by the replicas are collectively determined, based on the contributions made by a quorum of replicas, at least $f+1$ of which are not faulty.

KEY TERMS AND DEFINITIONS

Entropy: It is a measure of uncertainty, or randomness.

Message Authentication Code (MAC): A MAC is produced by a keyed secure hash function on a message. It is used to ensure the integrity of the message such that if a message protected by a MAC is tampered, it can be detected by comparing the MAC included with in the message and the recomputed MAC.

Pseudo-Random Number Generator: It is an algorithm used to generate a sequence of numbers that approximate the properties of random numbers. The algorithm depends on one or

a small set of initial numbers, usually referred to as the seed to the generator.

Quorum: A quorum of a set consists of the minimum number of components to perform a predefined function. In Byzantine fault tolerance replication, $2f+1$ is needed to form a quorum in a set of $3f+1$ replicas.

Random Number: It is a number generated by some process that cannot be reproduced or predicted.

Security: The security of a system refers to its capability of protecting itself from harm, such as external attacks. More specifically, a secure system is one that guarantees confidentiality, integrity, and the availability of the system.

Strong Replica Consistency: The states of the replicas of a process should remain identical at the end of the processing of each request.

System Integrity: The integrity of a system refers to the capability of performing correctly according to the original specification of the system under various adversarial conditions.

Threshold Cryptography: Basic cryptographic operations such as encryption, decryption, signature generation, and verification are performed by a group of processes without reconstructing the shared secret.

Data Visualization Strategies for Computer Simulation in Bioelectromagnetics

Akram Gasmelseed
Qassim University, Saudi Arabia

Ali H. Alharbi
Qassim University, Saudi Arabia

INTRODUCTION

Bioelectromagnetics is a branch of science that examines how living organisms interact with electromagnetic fields. In a broader sense, it is a discipline that spans the fields of signal processing, electromagnetics, medical imaging, physiology, medical physics, anatomy, occupational and environmental health, behavioral, and computer sciences.

Due to its provision of interactive and flexible programming environment, this chapter describes a LabVIEW based data visualization system that has been implemented and used in bioelectromagnetics simulations (Gasmelseed, 2013). The graphical nature of the LabVIEW programming environment makes it very easy to create a sophisticated application in a minimum amount of time, especially when compared to designing graphical user interfaces in a low-level programming language.

BACKGROUND

Bioelectromagnetics

Bioelectromagnetics is the field that depicts the interaction of electromagnetic (EMW) waves with biological systems (Furse et al., 2009). The Common core area of study in bioelectromagnetics includes the study of the interactions between electromagnetic waves and human tissue. Recent

advances in computational techniques have made it easier to assess the EMW behavior within the exposed biological tissue model numerically.

Computational techniques are extremely powerful for solving bioelectromagnetic problems and have been successfully employed in the modelling of microwave applicators used in hyperthermia (Polk & Postow, 1995; Maruyama et al., 2006), calculating electromagnetic signal absorption in human body models (Reyhani & Ludwig, 2006), and for dosimetry of mobile handhelds (Lin, 2006).

Laboratory Virtual Instrument Engineering Workbench (LabVIEW)

LabVIEW (Laboratory Virtual Instrument Engineering Workbench) is a National Instruments program development application (<http://www.ni.com/labview/>) with computational capabilities (e.g. analysis, visualization) similar to those found in C, Fortran or Matlab development systems (Samsi et al., 2010). LabVIEW is different from those applications in one important respect: other programming systems use text-based languages to create lines of code, while LabVIEW uses a graphical programming language called 'G' to create programs in block diagram form (Kalkman, 1995; Olansen & Rosow, 2001). LabVIEW also has extensive libraries of functions and subroutines for most programming tasks such as data analysis, data presentation, and data storage. LabVIEW includes conventional program development tools, allowing the user to set breakpoints, animate pro-

DOI: 10.4018/978-1-5225-2255-3.ch108

gram execution to see how data passes through the program and single-step through the program to make debugging and program development easier. Graphical programming is based on the concept of data flow, in contrast to the sequential logic of most text-based programming languages. This means that execution of a block or graphical component is dependent on the flow of data, or, more specifically, a block executes when data are made available at all of the block's input and output data are sent to all other connected blocks.

LabVIEW is a multithreaded programming language, so that specific operations within a single application can be subdivided into individual threads, each of which can theoretically run in parallel. For example, the block diagrams in LabVIEW are parallel programs. The LabVIEW compiler automatically breaks up these parallel programs into multiple threads for the user and passes these threads to the operating system for assignment to multiple processing cores. In comparison, text-based languages are sequential, that is, the code is basically run line by line.

Moreover, researchers in the field of bioelectromagnetics prefer to integrate C subroutines into MATLAB or Simulink code in order to speed-up their execution (Laakso & Hirata, 2012; Quinto et al., 2011). Integrating C subroutines with MATLAB or with Simulink is a difficult task and demands knowledge of the MATLAB MEX interface or the Simulink S-function interface.

On the other hand, in LabVIEW, C subroutine can be integrated using the code interface nodes (CINs) (Johnson, 1998). LabVIEW will create the prototype function headers and linking references, easing the insertion of the required C subroutine.

In this chapter, a LabVIEW development environment is designed to simulate those EM/biological tissue interactions. Two standard methods are presented to investigate the effect of electromagnetic radiation on the human tissue: the multilayered method, and the finite difference time domain (FDTD) method. The LabVIEW development environment provides a graphical user interface to the model that makes it easy to observe and modify the behavior of each element of the model, relatively easy to understand and they can be easily modified for the user's specific purpose.

METHODOLOGY

Multilayered Method

One of the standard methods to model EM signal absorption in human tissue is the multilayered method. The method is based on using simple planar models to solve the absorption problem. While these planar models may be simple, important properties of the absorption can be

Figure 1. General biological multilayered structure
Adapted from Akram & Jasmy, 2008.

illustrated (Akram & Andrew, 2006; Samaras & Christ, 2007).

Figure 1 shows the geometry of the problem. A plane wave travelling in the $+z$ -direction with the electric field $\vec{E}$ vector linearly polarized along the x -axis is incident upon biological multilayered structure.

The incident field is assumed to have harmonic time variation $e^{j\omega t}$. There are $N+2$ layers ($L_0, L_1, \dots, L_{N+1}$), and $N+1$ interfaces ($z_1, z_2, \dots, z_{N+1}$). The i^{th} layer indicated by L_i has permittivity ϵ_i [F/m], permeability μ_i [H/m], and conductivity σ_i [S/m]. Further, we denote the left-most layer (i.e. air) as L_0 , while we denote the right-most layer by L_{N+1} . Then, the electric ($\vec{E}_i$) and magnetic ($\vec{H}_i$) fields in the i^{th} layer are given by,

$$\vec{E}_i = (a_i e^{-j\gamma_i z} + b_i e^{j\gamma_i z}) \hat{x}$$

$$\vec{H}_i = \frac{(a_i e^{-j\gamma_i z} - b_i e^{j\gamma_i z})}{\eta_i} \hat{y}$$

where $i = 0, 1, \dots, N+1$. The constants a_i and b_i are the amplitudes of the incident and re-

flected waves, respectively, where the amplitude of the incident electric field is represented by a_0 , and is known in advance. γ_i and η_i denotes the propagation constant and the characteristic impedance at L_i , respectively.

The wave impedance is given by,

$$Z_i = \eta_i \frac{(1 + \Gamma_i e^{2j\gamma_i z_i})}{(1 - \Gamma_{i+1} e^{2j\gamma_{i+1} z_{i+1}})} \quad (5)$$

At the interface $z = z_i$, the reflection (Γ_i) coefficient is given by,

$$\Gamma_i = \frac{Z_i - \eta_{i-1}}{Z_i + \eta_{i-1}} e^{-2j\gamma_{i-1} z_i} \quad (6)$$

LabVIEW Implementation of Multilayered Code

To demonstrate our approach we have adapted an example that considers a multilayered biological structure (Karwowski, 2007) composed of three layers of tissues: skin, fat and muscle. In this simulation, the layered tissue model shown in Figure 2 is assumed to be irradiated by a 5.5 GHz plane-wave traveling in air, with the electric field component

Figure 2. Multilayered tissue model consisting of skin-fat-muscle

Figure 3. The block diagram that executes equations (5) and (6)

E_x having a unit magnitude, impinging normally at $z = 0$ on a tissue-air interface. LabVIEW's block diagram (shown in Figure 3) consists of a *for-loop*, *shift-registers*, and *array* tools.

Figure 4 shows results of computed electric field strength (1) obtained from LabVIEW program and MATLAB program.

Finite Difference Time Domain (FDTD) Method

The finite-difference time-domain (FDTD) method has become widely used for electromagnetic computation since the initial work of Yee KS (Yee, 1966) due to its power in solving Max-

well's equations accurately and efficiently within a highly scattering medium in a discretized form. The method uses a leapfrog scheme on staggered Cartesian grids where the electric field (E) is offset spatially and temporally from the magnetic field (H). This approach solves the present fields throughout the computational domain in terms of the past fields.

In this section, the FDTD method for a basic scattering modeling is presented (Akram & Jasmy, 2007). We present a one-dimensional (1-D) formulation with simple outer radiation boundary condition (ORBC) to avoid reflections from the edges of the modeling grid.

Figure 4. Comparison of computed electric field strength (E_i) in both (a) LabVIEW and (b) MATLAB

LabVIEW Implementation of One Dimensional (1-D) Formulation

To give a description of the FDTD method, initially a 1-D formulation will be used. Maxwell's scalar equations for a non-permeable (Taflov & Hagness, 2005) lossy medium ($\mu = \mu_0$, $\sigma^* = 0$) are,

$$\sigma E_z + \epsilon \frac{\partial E_z}{\partial t} = \frac{\partial H_y}{\partial x}$$

$$\mu \frac{\partial H_y}{\partial t} = \frac{\partial E_z}{\partial x}$$

These equations represent a plane wave with electric field oriented in the z -direction, the magnetic field oriented in the y -direction, and traveling in the x -direction. Equations (8) and (9) yield the discretized update equations when approximated by finite differences,

$$E_z^{n+1}[i] = Ca[i] \cdot E_z^n[i] + Cb[i] \cdot \left(H_y^{n+\frac{1}{2}}\left[i + \frac{1}{2}\right] - H_y^{n+\frac{1}{2}}\left[i - \frac{1}{2}\right] \right)$$

$$H_y^{n+\frac{1}{2}}\left[i + \frac{1}{2}\right] = H_y^{n-\frac{1}{2}}\left[i + \frac{1}{2}\right] + \frac{\Delta t}{\mu \delta} \cdot \left(E_z^n[i+1] - E_z^n[i] \right)$$

where the terms $Ca[i]$ and $Cb[i]$ are given by,

$$Ca[i] = \frac{1 - \frac{\sigma[i] \Delta t}{2\varepsilon[i]}}{1 + \frac{\sigma[i] \Delta t}{2\varepsilon[i]}}$$

$$Cb[i] = \frac{\frac{\Delta t}{\varepsilon[i] \delta}}{1 + \frac{\sigma[i] \Delta t}{2\varepsilon[i]}}$$

Equations (10) and (11) are easily programmed for solution by iteration of each equation. To illustrate the algorithm, a sinusoidal wave (1-GHz) propagating in a nonpermeable lossy medium ($\varepsilon_r = 1.0$, $\sigma = 0.005$ S/ms modeled) is used. The grid resolution ($dx = 2.5$ cm) is chosen to provide 20 samples per wavelength. The Courant factor $S = c \cdot dt/dx$ is set to the stability limit $S = 1$ to ensure numerically stable update in Equations (10) and (11). The number of grid cells (IE) in the x -direction is 200, and the total number of time steps is 240. A MATLAB program segment that executes time-stepping of E_z in the FDTD space lattice can be written as,

Figure 5. The block diagram of E_z field calculation

Figure 6. The front panel of E_z field calculation

$$E_z(2:IE) = Ca * E_z(2:IE) + Cb * (Hy(2:IE) - Hy(1:IE-1));$$

Following closely the LabVIEW instructions and using the FDTD model, the *block diagram* for E_z field calculation (10) (and shown in Figure 5) consists of a *for-loop*, *shift-registers* and *array* tools. The corresponding *front panel* for the E_z field calculation is shown in Figure 6 and Results of this programming construct are shown in Figure 7.

LabVIEW *Graphs* and *charts* are used to display data in a graphical form. *Graphs* and *charts* differ in the way they display and update data. *VIs* with graphs usually collect data in an *array* and then plot the data to the graph, which is similar to a spreadsheet that first stores the data and then generates a plot of it. In contrast, a *chart* appends new data points to those already in the display to create a history. On a *chart*, we can see the current reading or measurement in context with data previously acquired.

Recently, more sophisticated models were introduced and their aims is to provide a realistic human model. These anatomical-based voxelized inhomogeneous models are extracted from computed tomography (CT), magnetic resonance imaging (MRI) or X-ray scans (e.g. Visible Human (Spitzer & Ackerman, 1996) and Virtual Family (Christ et al., 2007)). In Matlab, creating a highly inhomogeneous model is very easy by providing to each array cell a material index and using indirect addressing of the updating coefficients.

In order to incorporate such models into LabVIEW applications, it is needed to use the IMAQ (image acquisition) Vision for LabVIEW (National Instruments Corp, 2007). IMAQ Vision for LabVIEW is a library of LabVIEW virtual instruments (VIs) that can be used to develop machine vision and scientific imaging applications.

FUTURE RESEARCH DIRECTIONS

The theory and simulation experiments in this chapter will lead to further understanding of electromagnetic interactions.

In future, research can be conducted to conveniently integrate DAQ cards in our software frame of LabVIEW. As a scientific issue, the interaction of electromagnetic energy with biological systems is hardly new, and such integration can be considered a novelty in scientific literature of research on electromagnetic interactions.

With DAQ integration and the availability of fast computers in modern times, we will be able to examine the electromagnetic interactions in real time.

CONCLUSION

Computer modelling will likely remain the best method to determine the electric fields inside body organs and tissues in many practical situations. There is a close relationship between the

Figure 7. The FDTD computed E_z and H_y at every time step

mathematical description used in the biological model and the computational method for solving the fields inside the model. Further, the availability of more powerful computers and refinement of computer codes will allow the determination of the fields inside the biological model in greater details and allow for more realistic models of EM emitting devices to be incorporated.

In this article, a LabVIEW development environment is discussed to simulate those EM-biological tissue interactions. Two standard methods are presented to investigate the effect of

electromagnetic radiation on the human tissue: the multilayered method, and the finite difference time domain (FDTD) method. The LabVIEW development environment provides a graphical user interface to the model that makes it easy to observe and modify the behavior of each element of the model, is relatively easy to understand and can be easily modified for the user's specific purpose.

The advantages of using the LabVIEW development environment are many. First, the graphical nature of the development environment makes it easy to create sophisticated applications in a

minimum amount of time, especially when compared to designing graphical user interfaces in a low-level programming language like C/C++. Moreover, the structure of LabVIEW makes it easy to add new components to the model when the need arises. The user interface allows the user to observe and gain insight into the behaviour of the model. Finally, VIs has both an interactive user interface and a source code equivalent and they accept parameters from higher-level VIs.

KEY TERMS AND DEFINITIONS

Bioelectromagnetics: A branch of science that describes the interaction of electromagnetic (EMW) waves with living organisms.

Computational Techniques: The techniques that use computers to analyze and solve scientific and engineering problems.

Dosimetry: The measurement and assessment of the absorbed electromagnetic radiation in biological tissue.

Finite-Difference Time-Domain (FDTD): A mathematical technique used for finding an approximate solution to differential equations used in various areas of applied sciences.

LabVIEW: An acronym for “Laboratory Virtual Instrument Engineering Workbench” and is a development environment for a visual programming language from National Instruments (NIs) designed for every engineer and scientist to solve real world problems compared to text-based programming (e.g. Matlab, C).

Multilayered Method: A technique used in electromagnetic analysis to determine the absorbed power in a one-dimensional biological model which has been arranged into several distinct tissues layers with different intrinsic properties using transmission line analogy.

Outer Radiation Boundary Condition (ORBC): A condition that is needed to be satisfied at all the outside edges or surface of the computational space domain in which a set of differential equations is to be solved.

Ergonomic Design of a Driver Training Simulator for Rural India

Prabir Mukhopadhyay

Indian Institute of Information Technology Design and Manufacturing Jabalpur, India

Vipul Vinzuda

National Institute of Design Gandhinagar, India

INTRODUCTION

Hired cars (taxi) have become popular in the rural areas of Gujarat state in India for commuting, leading to an increased demand for taxi drivers. To improve the lifestyle of the rural population, the local government in Gujarat state of western India has taken an initiative. Their focus is to improve upon the transportation facilities for the people in these areas. The first step is to increase the number of hired cars (known as taxi locally) in different routes. This was a long standing demand of the people as buses and similar modes of public transportation are not popular in this part due to variety of reasons like high operational cost, absence of metallic roads etc. Thus there is an increase in demand of taxi drivers. To train the driver's new car driver training schools are opening up in these areas. This is serving two major purposes; first improving the connectivity between different places and second providing employment opportunity for the local youths. The youths are also keen on taking up driving as a mode of earning as it is lucrative when compared to agricultural work (which requires lot more physical labor) and many are supplementing their income from agricultural work by driving part-time. The local government has come up with schemes for providing soft loans to these youths for purchasing their own cars. The cars that ply in these areas are the standard cars manufactured indigenously in the country and the government rule does not

permit cars of any other manufacturers to ply in these routes.

As training and issue of licenses for these drivers necessitate the applicant to go through successive training on simulators followed by training on the roads, simulator training is becoming an important aspect of the driving schools. The simulators are mainly imported from the western world and are installed in the schools. Hence the novice drivers are trained on a simulator, which does not give them that confidence of driving on rural Indian roads, which are different from the western world. On repeated requests from the trainers, alumni of the driving schools, novice drivers, and other stake holders, ergonomic analyses of the existing simulators were done to reveal mismatches in the traffic conditions of the rural India and the western roads. There were various problems with the existing configuration related to comprehension (88%), readability (92%), navigation (89%), error messages (96%) and feedback menu (69%). Based on users feedback new simulators were designed.

BACKGROUND

Around 65% of the total population in India lives in the rural areas. Growth and prosperity of the country is largely dependent on these areas, with employment for the local youth becoming a challenge (Mukhopadhyay, 2006). It has been reported that (World Bank, 2000) 74% of the rural

population in India are still not integrated into the national economy due to lack of proper transportation facilities. Thus better transportation in rural India is a necessity as it gives the rural people an opportunity to travel for different purposes like health, education, social purposes and services (Ramaswamy, 1998). Thus focusing on rural local youths as taxi drivers.

It has been established that simulator training plays an important role in the training of a novice driver. For example it was found that while training car drivers on a simulator, the simulated environment was (Underwood et al., 2011) capable of increasing the hazard perception of drivers, thus indicating its criticality in driver training. There have been quite a few studies to indicate that the data from simulator training was very close to that of training in actual environment (Hallvig et al., 2013, Antonsen et al., 2014, Chan et al., 2010, Hallvig et al., 2013). For example in a comparative study (Hallvig et al., 2013) on sleepy driving on the real road and the simulator it was found that for both real and simulated driving the response to night driving appeared to be similar for subjective sleepiness and sleep physiology. In a study on the effect of landscape, different objects and landmarks on the driving behavior, it was found that the presence of any object on the road had a speed reducing effect which was in line with the simulator data. It was further established in the same study that different objects, land marks and landscapes affected the driver behavior in similar manner, both on the simulator and in the actual environment. Similarly another group (Antonsen et al., 2014) reported that open landscapes encouraged the drivers in actual environment to drive fast, and the drivers reported less stress compared to other conditions of the road. This was again very similar to the data obtained on the simulator. Another utility of the driving simulator is that it is useful (Chan et al., 2010) in evaluating certain driving attributes of the novice drivers like hazard anticipation, speed management, and attention maintenance. So these studies indicate that driving simulators are an essential tool in the training of

novice drivers. For the training to be effective, it's important that the simulated environment should be close to the actual driving environment of rural India which is different from the western world.

Research has indicated that there are hazards (Gurr et al., 1998) associated in transferring any technology without due considerations of the local culture, as this goes against ergonomic norms and leads to mismatch at the user interface which in turn leads to error. Safety and culture of a geographical region determines what specific problems pertaining to drivers training need to be addressed. So it is important to take feedback from the local end users about the exact features of the driving world which should be incorporated at the simulator interface, so that the novice drivers get a more realistic feel of the driving environment. This research was an attempt in that direction, to do an ergonomic analysis of the existing simulator interfaces and suggest suitable concept designs in tandem with the Indian traffic system in rural areas. Technology today is a traveller. It is conceived in one country, manufactured in a second country and implemented in a third country. Thus time has come for customization of the user interface which is the front end of any technology, in tandem with the target users of the target. This is not only pertinent in the Indian context but similar context where a foreign technology is often imposed as an implant in different context.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Driving in rural India is a different experience than anywhere in the world. Majority of the roads are made of mud, traffic lanes are few, surprises on the roads like cows sitting, and kids playing are many. Apart from this there are issues of low illumination and waterlogged roads. Thus driving in rural India requires a different type of training and the same training simulator used to train prospective drivers in the west will not work in the

Figure 1. Existing simulator console

Indian rural scenario. The rural scenario is much more disorganized when compared to the western counterpart. The current research focused on the car simulator for the only brand of car which was currently used in this part of the country as public carriers. The emphasis was to train rural people and get them accustomed to the driving environment so that chances of mistakes and accidents are minimized when they train on real training cars. The simulator under study had two LCD screens (Figure 1A-B) which modelled the windshield of a car with a seating system along with gears and accelerators like that of a standard car. Participants were investigated while on the simulator so

that they are able to give actual feedback on the problems faced by them.

Study Design

Five different methodologies were applied. Direct observation and activity analysis along with still and videography recorded all the different activities of the participants at the existing simulator interface. Questionnaires were applied on the participants for the existing configuration. Scores were applied on the participants for the existing as well as the two concept designs. Subjective testing for usability of the interfaces for the existing

as well as the two concept designs was applied. Finally objective testing for performance, namely total time taken and the number of errors made for a set task was again applied on the participants for the existing and the two concept designs.

Participant Selection

Thirty-three right-handed male participants were selected for the study and had acquainted themselves with the simulator for the past fifteen days. The reason for fifteen days was the tenure of a course/training on a simulator; then they were trained on a training car. Only males were selected as in rural India females do not drive a taxi.

Qualitative Analysis

There were in total 28 observations, which were made by the research team. The entire team comprised of two members both trained in ergonomics. Each member was instructed to observe the activities of the driver from the beginning till the end. These were similar to other studies done to train drivers (Waard et al., 2008). The observational study started from the moment the driver boarded the simulator and the simulator started. All tasks performed by the driver, from the way he holds the handles to get inside the car, takes his seat, activates different controls, adjust the rear view mirrors were observed. There was special focus on the stages in which the participants became confused or made mistakes.

Questionnaire Study

A twenty questions survey questionnaire was administered to the participants to gain insight into the different types of problems encountered. It was ensured that other passengers and staff were not around, to ensure that people nearby did not bias the users. Some of the 20 questions were related to age, difficulty in accessing different controls, problem in reading and comprehending different

displays, difficulty in navigating under different adverse conditions of the road etc.

Interface Analysis

Different types of control and display elements on the simulator console were analyzed for usability issues such as placement, size and shape, graduations, color etc. to name a few. The ergonomic design issues for each of the interface elements were studied in detail. Rating scores were used to test the existing configuration and the concept designs. These scores were done on different sets of criteria based upon the feedback received from the trainers and taking lead from similar works reported in the literature (Stevenson et al., 2000). The first set of score criteria was “Comfortable to Use” or “Satisfactory”. The second set of score criteria was “Awkward” or “Very Uncomfortable”. The users were asked to rate the concept design on the basis of these two quantifiable questions. The percentage of total responses for different interface features was recorded. The third set of scores involved four levels in terms of perceived usability (Sade et al., 1998). These were “Good”, “Minor Problems”, “Major Problems”, “Failure”. “Good” indicated that participants did not have any problem at the interface. “Minor Problems” indicated that participants were occasionally confused which slowed down their performance. “Major Problems” indicated that participants encountered serious problems that slowed down their performance considerably. They were confused with the basic function of the concept design. “Failed,” indicated that participants were not able to operate. These scores indicated the total number of participants who agreed to these four levels in terms of perceived usability. A participant was allowed to give multiple responses.

Performance Analysis

Two dependent variables: total time taken and the number of errors made, were selected for objectively measuring the performance of the existing

Table 1. Demographics of the participants (n=33)

	Age (Years)	Experience (Months)
Mean	30.4	2.1
SD	7.9	0.7
Range	21-47	1-3

and the two concept designs. Participants were given a set task and were asked to perform it on the existing and the concept design interfaces. The total time taken and the number of errors made in performing the tasks were recorded.

Participants

The mean age of the participants (Table 1) was 30.4 years (± 7.9) with age ranging from 21 to 47 years old. The mean experience of on road driving was 2.1 months (± 0.7) with experience ranging from 1 to 3 months.

RESULTS AND DISCUSSIONS

The driving simulator had two major components. The physical component and the software user interface component. The later was imported from the west. The integration of the hardware and software again took place at the local vendors place. The physical component consisted of a seat without any doors and a dash-board (Figure 1B). There were three LCD screens in front where the simulation was displayed (Figure 1C). There was no haptic feedback from the gears, breaks or pedals of the car. In fact, the seat-belt which teaches the first safety aspects of driving was without any feedback when it was attached (Figure 1D). This was necessary as all the cars in this part of the country, which are used as taxi, have a feedback for seat belt on the dashboard. There was complete absence of any surrounding sounds to create the ambience of traffic or driving on a typical Indian road.

The interface of the simulator could be divided into two categories: the first one was the login and subsequent screens and the second one comprised of the main menu which was further made up of six sub- menus (Figure 2) in different permutations and combinations of the driving environment (Figure 3). After a successful login, users were able to go to the main menu, which contained six driving modes (Figure 3). The first one was day- time but with low illumination level. The second one was with precipitation of different types ranging from low to high. The third one was with hazards on the road. There were onscreen indicators with arrows and text messages indicating the position of the vehicle on the road as to whether it was in the appropriate lane and whether at a safe distance from other vehicles. The participant had to log in after their session was over to check their scores and then close the programme. The main problem with the interface was that it never mimicked the Indian road conditions and was representation of the western world.

The questionnaire study on the problems at the interface (Figure 4) revealed five major elements. 88% of the participants had problems in comprehending the information conveyed by the display in general. 92% of the participants were not able to read many of the pieces of information presented to them. There was difficulty in navigating through the menu structures reported by 89% of the participants. Error messages were not comprehensible (96%) and so was the feedback menu for 69% of the participants.

The overhead and rear view mirrors (virtual) were small in size, and placed outside the driver's visual cone thus rendering them virtually useless while driving the simulator (Figure 1C). The speedometer was not properly color coded for different speeds, thus it gave the driver no clue as to the safe driving speed (Figure 1D). The overall look and feel of this simulator interface was more like that of a video game and not at all similar to the Indian road conditions. On the roads few Indian- made vehicles were shown, but the roads were representation of the western world. The

Figure 2. Existing user interface of the simulator

C

interface lacked “Indian” elements on the roads like potholes, grazing animals, moving traffic in wrong direction, people crossing, or vehicles changing lanes without warning. Another major drawback of the interface was the driver’s feedback system. There was no facility for taking a print-out of the feedback which could be referred to later for improving performance. In fact the manner in which the feedback was given to the users was not comprehensible to many because it received few satisfaction scores from the users. The users expected the mistakes in terms of percentage of the total navigation rather than in absolute num-

bers. A complete comparative analysis of all the features of the existing and the concept designs (1 and 2) are represented in Figure 3.

The main features of this concept (concept design 1) were that (Table 2) the mouse platform was removed to ensure free movement of the left hand when operating the gears. The instrument clusters were redesigned with a contrasting color (Figure 5). The main menu configuration was provided in the console of the dashboard itself (Figure 6). For the interface part (Figure 7) the selection menu was split up into discrete steps with images to facilitate the ease of selection.

Figure 3. Comparison between the existing and the two design concepts of the simulator interface

Configuration Selection Menu 1			
Configuration Selection Menu 2			
Driving scenario 1			
Driving scenario 2			
Feedback menu			

The different menu options like mode and traffic, visibility and time of the day were combined and chunked together based on their relevance. The participants were guided by a blinking cursor for moving to the next option, before moving to the

next screen. When an option was selected it was highlighted by a bright green color. The “next” button was enabled only when all the options on the screen were selected.

Figure 4. Percentage of participants that mentioned a problem for different ergonomic issues at the existing interface

Note: As there were multiple responses the total does not add up to 100.

Figure 5. Comparison between the existing and the proposed design concept of the instrument panel

Table 2. Ergonomic design features of design concept 1 of the simulator console panel

Features
• Using the existing cab arrangement with ergonomic updates • Bigger screen with better orientation • Mouse platform is removed • Main menu configuration is provided in the console of the dashboard • Redesigned instrument cluster • Cluster- includes gear shift and seat indicators and colour zones • Trip meter • Steering is provided with tilt and height adjustments
Salient Features
• Using existing cab- cost is minimal • Using the center console already available in cab • Bigger screens • Height adjustment steering will provide better viewing angle

SOLUTIONS AND RECOMMENDATIONS

After analyzing the problems two concepts were developed. The main features of the first concept (concept design 1) were that (Table 2) the mouse platform was removed to ensure free movement of the left hand when operating the gears. The main menu configuration was provided in the console of the dashboard itself. The instrument clusters were redesigned with a contrasting color (Figure 5 and Figure 6). For the interface part (Figure 7) the selection menu was split up into discrete steps with images to facilitate the ease of selection.

For the physical part the dashboard (concept design 2) was recreated (Figure 8 & 9) and Table 3. Two seats were provided like a real training car. A bonnet was fabricated to train the participants

Figure 6. Proposed layout of the console and the instrument cluster: design concept 1

on making a judgment on the road. This was essential as this category of taxis has a bonnet, which comes in the visual field of the drivers with shorter torso. For this concept (design 2), (Table 3) similar scenarios were developed. The screen here consisted of a timer to indicate how much time the user has spent on the simulator, along with a “pause” and a “home button”. Here also fifteen feet is considered a safe distance between two vehicles on the road. Unlike the previous concept design, there was no change in color to indicate whether the vehicle is coming in proximity to another vehicle on the road. Instead an icon at the center was provided based on the expected quadrant of the visual field, with text indicating whether one was at a safe distance, needs to keep a safe distance or is too close to a vehicle.

Table 3. Concept-2 ergonomic design features of the simulator console pane

Features
• Recreating the car dashboard • Two seats- instructor sits along with the driver in a closed cabin arrangement • Bonnet mock-up is provided to get a sense of stopping and starting • Single curved screen is used- avoiding distortion of imagery • Passenger side glove box modified to hold a keyboard and mouse • Steering provided with tilt and height adjustment
Salient Features
• Instructor can also sit inside the cab at all times • Provision of mouse and keyboard • Curved screen- better viewing angle • Printed feedback form- better assessment

Figure 7. Proposed interface of design concept 1

C

Figure 8. Proposed layout of design concept 2(exterior) and the layout of the console (below) with the design of the instrument cluster remaining the same as in design concept 1

Figure 9. Comparison between the existing layout of the simulator console with the two new design concepts for the console layout

As the user study revealed the need for contextualizing the interface to Indian conditions, different scenarios were developed (Figure 9) for this purpose. Six different types of scenarios were framed, and on these scenarios (Figure 10) different types of vehicles were placed. The six major scenarios were city (representing any modern Indian city) with wide roads but haphazard placement of billboards and with traffic rules being violated by other vehicles. The second scenario was a typical non-metallic mud road as found in rural and semi-urban India. The third scenario depicted a traffic signal on an asphalt road popularly known as metallic road (this is where maximum violation of traffic rules happens, and maximum accidents take place). The fourth scenario depicted surprises such as stray animals on the road, which are very common features in the Indian roadway context. The fifth scenario depicted roundabouts, which in India are again an extremely vulnerable zone for road accidents including collision and overturning of other vehicles like three-wheelers. The sixth scenario depicted vehicles being driven on the wrong side of the road which is extremely important, as a good driver needs to be extra vigilant to prevent casualties on the road. A separate driver's feedback form was developed and the users could carry a printout of the same for their reference (Figure 11). The information (number of errors for a set task) was structured as per users feedback with the mistakes represented in percentage of the total travel time. Driving in rural India entails travelling through stretches of semi-urban areas as well, thus such areas were

deliberately included in the concept designs to make it more realistic.

The users rated different interface elements in the new designs for the two layouts in comparison to the existing layout (Figure 2). The scores for "Comfortable to Use" or "Satisfactory" for "simulator loading" were higher (Figure 12) for concept design 1(88%) and concept design 2(92%) compared to the existing configuration (03%). The scores for "password log in" were again higher for concept design 1(92%) and concept design 2(98%) compared to the existing one (01%). The scores for "main menu" for concept design 1(87%) and concept design 2 (91%) showed similar trend as well. For "driver menu" concept design 1(89%) and concept design 2(88%) again scored over the existing configuration (12%). "Hazard preparation" for concept design 1(91%) and concept design 2(94%) was higher than the existing one (4%). The other element like "on screen error messages" for concept design 1(89%) and concept design 2(90%) was again more than existing (3%). Similarly for "feedback menu" it was higher for concept design 1(92%) and concept design 2(94%) compared to the existing one (9%). To compare the scores between the existing interface and the newly developed concept designs 1 and 2, a One-Way Analysis of Variance (ANOVA) was applied on the scores for "Comfortable to Use" or "Satisfactory" for the existing configuration and concept designs 1 and 2. The scores were significantly different from one another ($p < 0.001$). To differentiate between the scores for different designs, Student-Newman-Keul's tests were performed on the existing configuration as well

Figure 10. Proposed interface of design concept 2

A.

B.

Figure 11. Comparison between the online feedback form and newly designed form in print format for drivers

Figure 12. Participants (%) rating the existing and the concept design interfaces as “Comfortable to Use” or “Satisfactory”

as concept designs 1 and 2. There was no difference in scores between concept designs 1 and 2, but for the existing configuration the scores were significantly ($p < 0.05$) lower than concept designs 1 and 2.

The scores for “Awkward” or “Very Uncomfortable” (Figure 13) for “simulator loading” was at 91% for the existing configuration, but decreased to 2% for concept design 1 and 8% for concept

design 2. For “password log in” the score for the existing configuration was at 90% whereas for concept design 1 it was 9% and for concept design 2 it was 6%. Along similar lines for “main menu” the score for “existing configuration” was at 88% which declined to 8% for concept design 1 and 5% for concept design 2. The scores for “driver menu” for the existing configuration was at 87% but declined to 7% for concept design 1 and 7% for

Figure 13. Participants (%) rating the existing and the concept design interfaces as “Awkward” or “Very Uncomfortable”

concept design 2. A similar trend was observed for “hazard preparation”. For the existing configuration, the scores were at 79% which declined to 6% for concept design 1 and 2% for concept design 2. For “on screen error messages” the scores for existing configuration were at 83% and for concept design 1 at 5% and concept design 2 at 5% again. The “feedback menu” followed similar trends. It was 91% for existing configuration and 4% for concept design 1 and 4% for concept design 2.

A One-Way Analysis of Variance (ANOVA) was applied on the scores for “Awkward” or “Very Uncomfortable” for the existing configuration and concept design designs 1 and 2. The scores were significantly different from one another ($p < 0.001$). To differentiate between the scores for different designs, Student-Newman-Keul’s tests were performed on the existing configuration as well as concept designs 1 and 2. There was no difference in scores between concept designs 1 and 2, but for the existing configuration the scores were significantly ($p < 0.05$) higher than concept designs 1 and 2.

For the existing (Table 4) configuration the scores for “Good” and “Minor Problems” were at 0. For “Major Problems” it was at 11 and for “Failure” it was at 5. For concept design 1 the scores for “Good” was at 12, “Minor Problems” and “Major Problem” at 2. For “Failure” it was at 0. Similarly for concept design 2 the score for “Good” was at 14, “Minor Problems” and “Major Problems” it was at 1. For “Failure” the score was at 0.

Table 4. Performance comparison with the existing and the design concept interfaces. The numbers below indicate the number of users who responded.

	Existing Interface	Concept 1	Concept 2
Good	0	12	14
Minor problems	0	2	1
Major problems	11	2	1
Failure	5	0	0

N.B.: As there were multiple responses the total does not add up to 33 in many cases, 33 being the total sample size. Zero indicates that subjects did not comment on that particular level of perceived usability.

A measure of performance was also conducted on the existing configuration and the two concept designs. Two dependent variables were selected, one was the total time taken (minutes) to perform a set task and the second was the number of errors made in performing the task. The mean time taken for the existing configuration (Table 5) was 77.9 minutes ($SD=9.1$). For concept design 1 it was 64.4($SD=15.6$) and for concept design 2 it was 75.6($SD=15.8$). A One-Way Analysis of Variance (ANOVA) was applied on the mean time for the existing and the two new concept designs. The mean performance time for the existing configuration, concept design 1 and concept design 2 were significantly different from one another ($p < 0.024$). A Post Hoc Students-Newman Keuls test revealed that the scores for the original configuration were significantly higher than concept designs 1 and 2

Table 5. Total time taken and number of errors made at the existing and the design concept interfaces for performing a set task

	Existing Interface	Concept 1	Concept 2
Time in Minutes			
Mean (SD)	77.9(9.1)	64.4(15.6)	75.6(15.8)
Range	66-91	33-99	40-94
Error (Number)			
Mean (SD)	19.4(6.4)	5.1(2.2)	8.1(1.6)
Range	11-40	2-9	6-11

(at $p < 0.05$) with the existing configuration taking the maximum time followed by concept design 2 and then concept design 1. The second measure of performance was the number of errors made. These errors were defined on the basis of the number of mistakes the participants made as discussed in the methods section. For the existing configuration (Table 9) the mean errors were at 19.4(SD=6.4). For concept design 1 it was at 5.1(SD=2.2) and for concept design 2 it was at 8.1(SD=1.6). A One-Way Analysis of Variance (ANOVA) was applied on the error rate for the existing and the two new concept designs. The mean error rate for the existing configuration, concept design 1 and 2 were significantly different from one another ($p < 0.001$). A Post Hoc Students-Newman Keuls test revealed that the error rates for the original design and the two concept designs 1 and 2 were all significantly different from one another (at $p < 0.05$), with the existing configuration yielding the highest number of errors followed by concept design 2, then concept design 1.

FUTURE RESEARCH DIRECTIONS

Simulator of similar nature could also be designed for training the novice drivers in other domains of public transportation in India like motor boat, tram, three wheelers etc. so that they are confident before they start driving the real vehicle. The present study could also be extended for screening of older drivers for these types of vehicles. It has been established that the existing screening system for older drivers (medical test, road test, cognitive screening) is unreliable (Casutt et al., 2014). Thus further work on this type of simulators could be directed in this direction so as to ensure that drivers who get old are capable of driving safely.

This research could be extended to other domains like medicine, aerospace, communication etc. where many a times the technology is

imported from a different country and is used by the target users in a different country without any customization of the user interface in tandem with the local users and the context. Such research into identifying mismatches at the user interfaces would be interesting to probe into in terms of the exact location, nature and quantum of the ergonomic or human factors problems.

CONCLUSION

The participants accepted the new concept designs of the car simulator in the Indian context in principle. There were some minor problems related to information design, which were auditory feedback (which needs further development as it was very soft), road signage (which needs refinement considering night time driving and driving during heavy rainfall) for which work is ongoing. The simulator and if it meets preference standards has to be now developed as a working concept design and then tested on participants once again to see how it functions.

The research carried out here depicts the importance of humanizing technology in tandem with the target users and the local context in which it is to be used. In this era of globalization, when technology is conceived, developed and finally used by the target users in different geographical locations of the world, it becomes extremely important to customize the technology for the local context in order to reap the maximum benefit out of it. The study on simulator in this paper was an example in that direction, pointing to the fact that each technology developed in remote locations needs customization for the target users.

KEY TERMS AND DEFINITIONS

Feedback: The output from the machine to the user which makes the user at ease with the machine he is operating at.

Interface: It is the connecting link between the user and the technology with which he is interacting.

Mental Model: It is the image in our brain of what we see in real life. This image persists even after a long time.

Participants: They are the people who participate in the experiments.

Scenario: This is the artificial creation of a particular situation in order to test the robustness of any design meant for the users.

Simulator: A device which gives similar feedback to the users like the original product so that novice users get an experience of how the actual product works.

Usability: It is the ease with which a product can be used by the users for fulfilling their specific needs.

3D Scanning and Simulation of a Hybrid Refrigerator Using Photovoltaic Energy

INTRODUCTION

In this chapter, a methodology that starts with the measurement and recording of real prototype geometries up to simulations to evaluate parameters, improvements or performance under various conditions is proposed. Here it is presented a case study of a solar powered refrigerator with storage capacity for 50 kg of fruit. The refrigerator comprises two systems, vapor-compression and

Peltier. The methodology consisted in acquiring by a 3D laser scanner or Coordinate Measuring Machine (CMM) and in some small complex items using a 3D photogrammetry scanner (James, 2017; Ozdarici-Ok, 2015). These data were transferred first as a CAD or SolidWorks® geometry and subsequently transferred to domains geometry useful for ANSYS or COMSOL simulation software. These models with high-resolution brings the simulations closer to real prototypes. As a

DOI: 10.4018/978-1-5225-2255-3.ch110

source of direct information from the prototypes, thermal images obtained using a thermographic camera were taken. Also, wireless sensors were installed for temperature and humidity monitoring. The analyses of the energy efficiencies of both prototypes were performed. The idea of presenting this methodology is to demonstrate that it is possible to apply it in various prototypes regardless of sizes, geometries or whether they are or not solar powered.

The work seeks to develop a hybrid cooling system based on a system of traditional compression system and a Peltier cooling system. The construction or production of this system is focused on being able to assist the agribusiness sector that is away from the public electric network, directly in the crop areas, proposing that this system will be powered completely by photovoltaic modules and in turn, be able to innovate with the cooling systems adaptations.

The starting point was a commercial compression system, to build or make an approach of the required refrigerator with a capacity of 50 kilograms. The material used in the Peltier cooling system consisted of: four Peltier modules of 50 W, eight heat sinks and eight fans that assist with the distribution of heat within the refrigerator.

The following steps were the elaboration of the construction drawings, drilling and placing of the Peltier systems, in a distribution geometry designed in the SolidWorks® software. All the parts were put in place both physical and mechanical. Some of them were affected during the modification process. The geometry was acquired and exported for its analysis in a virtual simulation module of finite element (Work Bench ANSYS), to obtain a validation or improvement of the system with the efficiency of space and location, considering the fluid dynamics and thermodynamics.

A general scanning was conducted for a commercial refrigerator with a laser system (ZX 800 Corp) and, for the smaller parts, with a system of photogrammetry (PicoScan Pro). The scannings

were conducted using these devices for the development of a virtual 3D modeling. In this process, a polygonal mesh was applied to the virtual model initially constituted only of a point cloud (Bici, 2014), which is transformed into a file compatible with the simulation software.

Once that the process with the commercial refrigerator model reaches the simulation stage, the methodology is applicable to the construction and adaptation of the Peltier system using as a guide the electrical drawings previously made. To achieve a relationship between the Peltier system and the compression system uses a temperature sensor programmed to monitor the functioning of these systems on the basis of specific conditions known during the simulation process.

BACKGROUND

Design and Computer Aided Engineering

Design is an activity that is projected toward the solution of problems in the process of adaptation to the environment that surrounds it, for such purpose resources as the technology CAD/CAE are used. The most developed technique in Computer Aided Engineering (CAE) is the application of Finite Element Analysis (FEA) that, with the improvement of computers has become more accessible to all users. These techniques are used industrially from design to manufacturing getting optimize costs, quality, time, security, etc.

The implementation of the CAD software in engineering includes the development of synoptic charts, diverse kinds of diagrams, statistical graphics, standard representation of parts for its design and construction, tridimensional representation of dynamic models in multimedia, finite element analysis, applications in virtual reality, robotics, etc.

Figure 1. Puller and refrigerator motor

Table 1. Characteristics of the refrigerator

Refrigerant	TYPE R-134 a
Rated Voltage	115V
Rated Frequency	60 Hz
Current Rating	2.7 A

Cooling Powered by Photovoltaic Panels

At present, the cooling in the households represents more than 45% of the total electricity consumption, which is why on the basis of this challenge, solutions were found that represent a technological breakthrough where renewable energy acquired a very important role.

The challenges associated with this work is the distance that exists between the electrical distribution network and the crops of fruits. Therefore, the solution is the implementation of a photovoltaic system that meets the energy demand of the refrigerator. The refrigerator will be a field, for that reason, production losses are minimal during the fruit collect (as a model, guava was chosen).

This work deals with a refrigerator LINE HI SPEC (VR09) with the features shown in Table 1.

The cooling system is commercial, with a refrigerant *Type R-134 a* and a power of 310.5 W at 2.7A (Figure 1).

The solar panels for the power supply of the refrigerator had cells of 250 W at 24 V being monocrystalline panels with an area of 1.6 (Figure 2; Table 2).

Calculations and Batteries

To get the calculations, it is possible to start from the power demand that was required and the time in which it was engaged, multiplied by a factor of safety (Table 3).

There was a total of 2,916 W hr multiplied by the factor of safety: $2,916 \text{ W hr} (0.20) = 3,499.2 \text{ W hr}$. The batteries work at 12 V and the design implies several batteries in parallel to provide the required current.

Table 2. Features of the panel

Operation Voltage	24 V
Open Circuit Voltage	22 V
Current Rating	8 A

Figure 2. Solar panel 250W at 12V

Table 3. Characteristics of the batteries

Article	Consumption (W)	Time of Use (hr)	Daily Consumption (W hr)
Refrigerator	324	9	2916

$$\text{Amperes - hour/day} = \frac{\text{Watts} - \text{hr} / \text{day}}{\text{Volts}(\text{under})} =$$

$$\frac{3499.2}{24} = 145.8 \text{ Amp-hr day}$$

This is multiplied by the number of days of autonomy and divided between the depth of discharge:

$$\text{Amperes - hour/day} = \frac{\text{Amperes} - \text{hours} / \text{day} * \text{No autonomy days}}{\text{depth of discharge}}$$

$$= \frac{145.8 \frac{\text{Amperes}}{\text{hours}} * 3}{0.4} = 1093.5 \text{ Amp-hrs/day}$$

To determine the number of batteries, a capacity is selected in the A-H manufacturer catalog. In this case 12v, 115 A-H:

$$\text{Not batteries} = \frac{1092.5 \text{ Amperes} - \text{hour} / \text{day}}{115 \text{ Amperes} - \text{hour} / \text{batteries}}$$

It is considered the installation in the state of Queretaro, México, latitude 20.6 °N and longitude 100.3 °W, and the worst conditions are with a solar peak at December of 4.4 hr/Day, as shown in Table 4.

Table 4. hr/day solar peak in México

State	City	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Max.	Min.	Avg.
Qro.	Queretaro	5	5.7	6.4	6.8	6.9	6.4	6	6.4	6.3	5.4	5	4.4	6.9	4.4	5.9

Peak current of the arrangement = (Amp-hr /Day average)

$$/ (\text{battery } \eta) / (\text{hr/Day peak solar}) = 145.8 \text{ Amp-hr /Day} / 0.8 / 4.2$$

$$= 40.5 \text{ A}$$

The number of modules in parallel is:

$$\text{Number of modules in parallel} = \frac{\text{peak current of the arrangement}}{\text{peak current module}} \text{ FS}$$

FS = safety factor that takes into account the aging and dirt. It is taken as 1.2

$$\text{No. of modules in parallel} = 1.2 * (40.5 \text{ A} / 8 \text{ (A)}) = 5 \text{ modules in parallel}$$

$$\text{No. of modules in series} = \frac{\text{system voltage}}{\text{nominal module voltage}} = \frac{24}{12} = 2$$

No. total modules = No. modules in series * No. modules in parallel

$$= 2 * 5 = 10 \text{ modules}$$

The controller, with specified rated current whose value is given.

Short circuit current of the system: circuit current module * number of modules in parallel * FS

$$\text{The short circuit current of the system} = (24 \text{ A}) (5) (1.25) = 150 \text{ A}$$

In the following list, it can be observed the actions carried out within the process of analysis of the structure to be able to reach the required data.

- Sizing and assessment of the prototype (refrigerator).
- Development and construction of the prototype in SolidWorks®.
- Assembly and installation of the prototype, taking into account Peltier cells.
- Scanning of the prototype through photogrammetry (Peak Scan Pro) for small parts.
- Scanning of the prototype using the laser system (ZX 800 Corp) for large parts.
- Development of reverse engineering (Bici, 2014; James, 2017; Ziadi, 2014; Lopez Herrejon, 2015; Thomopoulos, 2015; Ozdarici-Ok, 2014; Janik, 2014).
- Flow Simulation of the obtained solid.

In this section, you will be studying the hoped-for outcome and the way in which the project can be developed in a way that is efficient; it is important to have this point already that depart from here and are born all the ideas of optimization and improvement of processes.

The average of the prototype was obtained to perform the construction of the same, it is necessary that the measures were as accurate as possible since it is designed to be the closest to reality, to obtain the results with a minimum error rate.

Evaluation and Construction of the Prototype in SolidWorks®

In this part, this work presents a proposal, which is based on design portions of the refrigerator separately. One of the qualities of SolidWorks® is that when working separately (individual design of the parts), once drawn all the parts, they can be joined to form a single solid, which can be simulated without any problem.

Construction of the Refrigerator

This part of the work began creating a sketch in SolidWorks® of the refrigerator rectangular geometry, depending on its measured dimensions, continuing with an extrusion to give depth to the figure, thus creating the solid. With extrusion cuts, it is possible to segment the solid and giving a better form to the structure of the refrigerator (Figure 3).

Construction of Heat Exchanger in SolidWorks®

This part began creating a sketch, where the original geometry was an aluminum foil and using a linear array (operation to make a geometry on a repetitive basis) to be able to carry out the set and with an operation of extrusion create the solid foils.

The following step was to build the copper pipe that runs through all the leaves, where the refrigerant passes to make the heat exchange, creating

Figure 3. Prototype of the refrigerator (solid)

the pipes on one side of the leaf trespassing all the foils, according to the measured dimensions.

Between each tube there is an outbound turn which represents an elbow, it turns and follows the flow of the entire copper line (Figure 4).

To create details such as edges inside of the refrigerator, new sketches in the face were used in that places where the work continues and thus be able to shape that surface in 2D.

With different design, it was possible to carry out the various details and thus have a more comprehensive and closer to reality model (Figure 4).

Construction of the Heat Sink in SolidWorks®

This part was worked through the creation of different levels, which according to the obtained heights, represented each of them.

In the foreground, the fan was built, starting with a sketch of the form, subsequently completely extruding the rectangle to make the solid form, following with slices for extrusion, cutting some spaces and detailing the corners with round turns.

Then, the work was focused with the foils, in the same way, first creating a single sheet with the particular geometry and with a linear array and continue with the repetition of the form and thus all the foils were created.

The drawing in Figure 5 is the base where the Peltier cell was placed and by which two copper pipes crossed the structure making contact with the base.

Construction of the Ventilator and Molding

After measure the dimensions, the stage began creating the simple trapezium-shaped figure. The cuts were represented in Figure 6. The details such as the moldings and the grille where the fan is located were also created in different sketches, to create the solid, which was in the form of foil.

Figure 4. Heat exchanger (solid)

Figure 5. Heat sink (solid)

Figure 6. An extractor fan (solid)

The realization of this geometry was very critical because in this space the heat sinks and the Peltier cells going to be put. Therefore, each these parts was made with the greatest possible accuracy regarding to the real measured object.

The molding which is located below the fan was also developed with different sketches to make the moldings and the shape of the grid according to the measures.

It is worth mentioning that this is a detail to get a better view of the refrigerator, as this part was just to make it as similar as possible to reality (Figure 7).

Assembly of the Prototype Considering Peltier Cells

The following stage was for creating the assembly, adding all the created pieces according to their corresponding positions, which work by coincidence, distances, concentrics and thus be able to align all these figures.

Creating different levels according to the place where position relationship was needed, a sketch was created by adding constructive lines, which serve to punt in position each part.

With this, it can be seen an improvement in design making it more complex and detailed as seen in Figure 8, Figure 9 and Figure 10.

The construction plans were made for better positioning of each of the components (Figure 11).

Scanning of the Prototype through Photogrammetry (Peak Scan Pro) for Small Parts

Photogrammetry is a technology which is based on the scanning using triangulation; it is a technology that allows obtaining the desired object in a point cloud. The model used for this works, projects a pattern (which in this case was a small projector) on the desired object, the reflected light was picked up by a high-definition camera, leading to the reading of the shape in the form of points and transforming it into a point cloud.

Figure 7. Molding (solid)

Figure 8. Refrigerator assembly (solid)

After capturing some photos, the figure was recorded but it had to be cleaned of any noise that might have occurred in the process of taking the photographs. Here, noise refers to all the spots or areas out of real surfaces that appear as displayed imperfections in the image.

This was one of the ways in which it was possible to scan small objects for the final prototype. The work was focused in obtaining a model very close to the real object to improve the simulation,

Figure 9. Location of heat sinks (solid)

Figure 10. Heat sinks (solid)

which depends in part on how successful was the scan. The better was the scanning implied that it was very likely to have a simulation more related to reality.

Also, an objective of this work is the use in the crop field and improve the productive sector of agribusiness in those areas that are remote from the electrical grid (Thomopoulos, 2015). That is why, for the use of this equipment, it was necessary to conduct a scan of fruit, in this case the guava as a model fruit individually and in a group within a container, and to analyze the behavior or influence of this kind of fruits and their container in the refrigerator performance with the use of the Peltier cells.

The computer will scan in 3D varying the angle of view to be able to do the recording of the fruit (guava), and after the recording, conduct a test of simulation. It started by adjusting the work table where the recording took place, as the set should not suffer any movement during the scan process, to ensure a point cloud with enough quality. Two programs were used (Mephisto PEAK PRO and Mephisto Process), the first helps in capturing the photos according to the settings arranged before beginning the recording of the object and the second for post-processing the data.

It is necessary the system calibration, specifying the size of the step in degrees for rotating the object for taking the photos. Also, other parameters were specified such as the distance between the object, the camera and the projector, adjustments related the surfaces in case of being shiny or black, bodies with slight movements or completely static, among others.

The next step was taking the photos, as shown in Figure 12, Figure 13 and Figure 14. If the images of the object were very sharp, the process of reverse engineering could be very simple.

The Mephisto Process® program connects all the figures to form the figure as a point cloud, which was cleaned of all the noise (Figure 15).

Figure 11. Refrigerator level

Figure 12. Peak scan PRO

Reverse Engineering

Geomagic Design X

In *Geomagic Studio*®, the scan is acquired with several options of format types. The one that resulted very useful was the file with format “.PLY” (Figure 16).

The file that contains a polygonal mesh (is a construction based on the point cloud by which lines were drawn a link between each) was opened

with the software, which will allow a real geometry refrigerator. Once the object was in the program, the next step was to proceed with the cleanliness of the polygonal mesh with the option “Mesh Doctor”. This option allowed to clean, refine and fill the defects that appeared in the scanning.

In Figure 17, each of the options that has the Mesh Doctor were used to clean the mesh properly.

Each of the spaces was cleaned and filled and now can be seen shaded as “islands” at Figure 18.

Figure 13. Scanning guava 1

Figure 14. Scanning guava 2

Figure 15. Point Cloud (guava)

Figure 16. Geomagic Studio 1

Figure 17. Geomagic Studio 2

Figure 18. Geomagic Studio 3

The mesh was manually cleaned and comes with a conversion from mesh to a point cloud. The point cloud was used to remove the noise generated by the scan (only the noise that was seen with the naked eye, separated from the main geometry). The noise was eliminated, and a polygonal mesh was performed with the tool “warp”. This completed the procedure to clean the polygonal mesh (Figure 20).

The next step for the reverse engineering was to make the change from a polygonal mesh to a solid body, usually an object modeled in a virtual space with a design software is covered by a polygonal mesh on the surface. The reverse engineering starts from a polygonal mesh to obtain the solid scan.

Geomagic Design X®

In this software the reverse engineering process was terminated. It is the final step, which gets the real geometry and transform it to a solid. It is important to clarify that the polygon mesh and its

Figure 19. Geomagic Studio 4

cleaning is only a shell of a real object and can not act as a functional object in a simulation. For use such representation of the object, it is necessary to solidify the piece. Nonetheless, this could be a complicated part of the reverse engineering.

Figure 20. Geomagic Studio 5®

The following step continues with the importation of the polygon mesh, keeping with the format “.PLY”, to manipulate it. Once having the mesh, the next step was the section of the interactive alignment, since this program generates a series of drawings X, Y, Z in a three dimensional space (Figure 21).

Once that there was an alignment of the object, there were two steps to be able to do a reverse engineering.

Figure 21. Geomagic design X I®

Figure 22. Geomagic design X2

Auto Surface

This tool in the program allows to adjust a surface and refill a body by a polygonal mesh. It creates the solid from a mesh and, in this way, it can be used in reverse engineering, since the tool does all the calculations and adjustments. The polygonal mesh must be complete and without errors, completely cleaned of any noise (Figure 22).

Figure 23 shows the final result.

Manual Mode

To make an reverse engineering, it is necessary to starts with the polygonal mesh of a geometry to make a solid body. The envelope generated during the process is completely hollow. To be able to generate the solid body, the whole process of a reverse way, in other words, instead of generating the drawing in an X-plane and then convert it to a three dimensional body, it begins with a drawing (polygonal mesh) and creates a plane on the surface or the base of the real object. Once having a plane, it is possible to remove the drawing. The polygonal mesh can be fragmented into the necessary drawings. Once fragmented, the basis of the object represented by a pink shading, it is possible to go to a real drawing in color blue, and the tool “Auto sketch” allows to do the stroke in blue by avoiding errors in the sizes.

Once done the dimensional drawing in blue, it generates a reference axis or a vector of extrusion (Figure 24).

Figure 25 shows the reference plane for the removal of the real dimensional drawing of the scanning.

Taking the real drawing and generating it on a reference plane with extrusion in its normal

Figure 25. Reference Level, manual mode

direction (direction perpendicular to the plane), Figure 26.

Once drawn the vector of extrusion, it was possible to follow the creation of the solid base. There was the option to extrude. The base object was extruded to the desired dimension and the program can do it easily.

The process can be repeated as often as necessary. If it is a regular figure without any complex shape, the work is faster, but if it is a more complex piece, the process can take much more time. This step was done for each part of the object, in the case of requiring or desiring them to be separate elements, because it is possible to enable the op-

Figure 26. Base Level, manual mode

tion to prevent the union of the extruded areas and keep them as separate bodies (Figure 27). Once having the piece created by the method of extrusion, several tools were used to replace a polygonal mesh on the surface and create a set that fully-matched to the export a real geometry of the desired object (Figure 28).

Simulation in ANSYS

ANSYS is a third generation software. It is divided into three main tools named modules: pre-processor (creation of geometry and mesh), processor and post-processor. Both the pre-processor as the post-processor are fitted with a graphical interface. This processor for the finite element solution of mechanical problems includes: analysis of static

Figure 27. Drawings, manual mode

Figure 28. Final Geometry, manual mode

and dynamic structures (both for linear and not linear problems), analysis of heat transfer and fluid dynamics, as well as problems of acoustic, and electromagnetism. Normally, these tools are used simultaneously achieving mixed problems of structures along with problems of heat transfer as a whole. This software is also used in simulation software of civil and electrical engineering, physics and chemistry.

Once received the solid, it is transferred to ANSYS, where the behavior of the flows was seen according to the variables both, internal and external. It is worth mentioning that this simulation of flow was unique. In this simulation, the flows can be observed from the direction of the fans with air going up ↑ or the air going down ↓ (Figure 29).

Figure 30 shows a demonstrative flow simulation of the Peltier system with a configuration of flow going up ↑↑.

FUTURE RESEARCH DIRECTIONS

- The developed prototype can be scaled but require new adjustments for changes in geometry or capabilities.

Figure 31. Simulation 3

- The technological development and studies were made for geometry, loads and specific characteristics of use in rural areas.
- The vapor-compression combined with Peltier cells was proposed for the particular application of *in situ* utilization in the place of harvest.

CONCLUSION

Nowadays the use of renewable energy sources is a challenge, the acceptance of the society still has some difficulty, and it is for this reason that there are implemented projects that demonstrate the potential of this technology in the industrial sectors.

The agroindustrial sector is one of the most important sectors worldwide both, in size and for its strategical activity associated with the food production. Nevertheless, the crops usually are rural areas far from the urban electric network. For this reason, this work proposes the implementation of an autonomous refrigerator system using photovoltaic modules. The results demonstrated that performance is optimal giving rise to a considerable improvement, increasing the possibility to be applied in the agroindustrial sector or in any sector that has or dependent on mobile cooling systems.

From the tests performed and the compilation of the simulations, the efficiency achieved in the hybrid system is very similar to the commercial system, with the difference of temperature fluctuations which are smaller, there is a lower power consumption based on the reaction time and temperature.

The Peltier cells, useful for cooling by contact, have the disadvantage of requiring more current. As a result, there were almost no savings in power consumption in comparison with the compression system. However, the advantages of Peltier cells are important, the fact of being more compact or

smaller is very useful when deployed on mobile applications or facilities that need to be transported.

It is recommended that in the scanning process of the device, getting a sound recording would facilitate the process of reverse engineering. This technology is easily manipulable and it can be deployed in a wide variety of cases, which facilitates and improves the processes and data in time and accuracy.

KEY TERMS AND DEFINITIONS

Extrude: It refers to the creation of an object with three dimensions from a two dimensional drawing.

Hybrid Refrigerator: A device with two or more different kinds of systems for cooling or chilling, such as: Peltier, Vapor - Compression, Ammoniac – water.

Modeling: The transference to a virtual environment of an object with a 3D visualization.

Noise in Photogrammetry Images: It refers to all the spots or areas out of real surfaces that appear as displayed imperfections in the image.

Peltier Cells: Semiconductor devices that by an electrical current can cool or chill one of their sides and heat the other.

Photogrammetry: The obtaining of reliable measurements from photographic images. Also, a scanning method comprising the projection of a pattern and photo capture in its 360° of an object to make a three-dimensional reconstruction.

Point Cloud: Points at a virtual space resulting from scans that represent an object surface but only reconstructing the location of benchmarks or targets.

Polygonal Net: Surface film produced by nodules or triangulated areas for the geometries recording.

Refrigeration: The cooling or chilling of food at domestic or industrial uses.

Simulation: The imitation of behavior or performance of a real phenomenon or object using a software that represents the object imposing the initial and boundary conditions.

Solar Energy: The electromagnetic radiation coming from the sun absorbed and transformed into electricity to be used by electronic devices in human activities.

Vector of Extrusion: It is an imaginary line which creates a three-dimensional object through a flat base, by means of the vector or imaginary line, the object will acquire the direction and distance in three dimensions.

Uniform Random Number Generation With Jumping Facilities

E. Jack Chen

BASF Corporation, USA

INTRODUCTION

As computer capacities and simulation technologies advance, simulation has become the method of choice for modeling and analysis. The fundamental advantage of simulation is that it can tolerate far less restrictive modeling assumptions, leading to an underlying model that is more reflective of reality and thus more valid, leading to better decisions (Lucas et al. 2015). Simulation studies are typically proceed by transforming in a more or less complicated way of a sequence of numbers between 0 and 1 produced by a pseudorandom generator into an observations of the measure of interest. A facility for generating sequences of pseudorandom numbers is a fundamental part of computer simulation systems. Furthermore, random number generators also play an important role in cryptography. A collection of random variables $x_1, x_2, \dots, x_n$ is a random sample if they are independent and identically distributed. True random numbers cannot be produced by a deterministic algorithm, and hence, random numbers generated by using a recursive equation are referred to as pseudorandom numbers. The deterministic nature of these techniques is important because it can be reproduced in computations. A facility for generating sequences of pseudorandom numbers is a fundamental part of computer simulation systems. Usually, in practice, such a facility produces a deterministic sequence of values, but externally these values should appear to be drawn independently from a uniform distribution between 0 and 1, i.e., they are independent and statistically indistinguishable from a truly random sequence. Furthermore, multiple independent streams of

random numbers are often required in simulation studies, for instance, to facilitate synchronization for variance-reduction purposes, and for making independent replications.

A random number generator (RNG) is an algorithm that starting from an initial seed (or seeds), produces a stream of numbers that behaves as if it were a random sample when analyzed using statistical tests. The RNG is closely related to the Deterministic Random Bit Generators (DRBGs). See L'Ecuyer (1990, 2013) and references therein for more information on RNGs. We describe a portable set of software utilities for uniform random-number generation. It provides for multiple generators (streams) running simultaneously, and each generator (stream) has its sequence of numbers partitioned into many long disjoint contiguous substreams, see L'Ecuyer et al. (2002). Simple procedure calls allow the user to make any generator “jump” ahead/back v steps (random numbers). Implementation issues are discussed. The basic underlying generator CMRG (Combined Multiple Recursive Generator) combines two multiple recursive random number generators with a period length of approximately 2^{191} ($\approx 3.1 \times 10^{57}$), good speed, and excellent theoretical properties, e.g., the lattice structure, see Kroese et al. (2011) for a list of desired properties.

BACKGROUND

There are a number of methods for generating the random numbers, of which the most popular are the congruential methods (mixed, multiplicative,

DOI: 10.4018/978-1-5225-2255-3.ch111

and additive). The (mixed) linear congruential generators (LCGs) are defined by

$$x_i = (ax_{i-1} + c) \text{MOD } m, \quad u_i = \frac{x_i}{m}, \quad x_0 \in \{1, \dots, m-1\} \quad i > 0.$$

where m (the modulus) is a positive integer (usually a very large primary number), a (the multiplier) $\in \{1, \dots, m-1\}$ and c (the increment) is a nonnegative integer. This mathematical notation signifies that x_i is the remainder of $(ax_{i-1} + c)$ divided by m . Hence, $x_i \in \{1, \dots, m-1\}$. Thus, random variable u_i is a uniform 0, 1 variable. Note that

$$x_{i+v} = \left(a^v x_i + \frac{c(a^v - 1)}{a - 1} \right) \text{MOD } m.$$

Hence, every x_i is completely determined by m , a , c , and x_0 . The sequence x_i repeats once it returns to a previously visited value. The period of a generator is the length of a generated steam before it begins to repeat. If $u_0 = u_p$ (where $p > 0$), then the length p is called the period. The longest possible period for a LCG is m , i.e., m represents the desired number of different values that could be generated for the random numbers. Hence, the modulus m is often taken as a large prime number close to the largest integer directly representable on the computer (i.e., equal or near $2^{31}-1$ for 32-bit computers). If $p=m$, we say that the generator has full period. The required conditions on how to choose m , a , and c so that the corresponding LCG will have full period are known, see Knuth (1997) or Law (2014).

LCGs are sensitive with respect to the parameters, especially the value of a . When $c > 0$, the LCGs are called mixed LCGs. When $c = 0$,

$$x_i = ax_{i-1} \text{MOD } m, \quad u_i = \frac{x_i}{m}, \quad x_0 \in \{1, \dots, m-1\} \quad i > 0.$$

These LCGs are called multiplicative LCGs. Most existing implementations of LCGs are multiplicative LCGs, because in general the value of c does not have a large impact of the quality of an LCG. Note that if $x_i = 0$, then all subsequent x_i are identically 0. Thus, the longest possible period for a multiplicative LCG is $m-1$. Furthermore,

$$x_{i+v} = a^v x_i \text{MOD } m$$

Most experts now recognize that small LCGs with moduli around 2^{31} or so should no longer be used as general-purpose random-number generators. Not only can one exhaust the period in a few minutes on a PC (personal computer), but more importantly the poor structure of the points can dramatically bias simulation results for sample sizes much smaller than the period length.

One way of extending the basic LCG is to combine two or more LCGs through summation. Another way of extending the basic LCG is to use a higher-order recursion. A multiple recursive random number generator (MRG), which goes from integer to integer according to the recursion

$$x_i = (a_1 x_{i-1} + \dots + a_k x_{i-k}) \text{MOD } m, \quad u_i = \frac{x_i}{m}$$

$$A \text{ seed } x_0, \dots, x_{k-2}, x_{k-1} \in \{1, \dots, m-1\}$$

where i , k , and m are positive integers, and $a_1, \dots, a_k \in \{0, 1, \dots, m-1\}$. To increase the efficiency and ease the implementation, the MRG algorithm usually set all but two a_i 's to 0. Furthermore, the nonzero a_i should be small. However, L'Ecuyer (2013) points that these conditions are generally in conflict with those required for having a good lattice structure and statistical robustness. See Law (2014) on the lattice structure of pseudorandom numbers. The longest possible period for a MRG is m^k-1 (L'Ecuyer, 1996). Other way of extending the basic LCG is the additive congruential RNG (ACRON). The ACRON sets $a=1$ and replace

c by some random number proceeding x_i in the sequence, for example, x_{i-1} (so that more than one seed is required to start calculating sequence). Wilkmaratna (2008) indicated that the ACRON is a special case of a multiple recursive generator.

Other classes of RNGs are available, e.g., twisted generalized feedback shift register generators (Matsumoto & Kurita, 1994; Matsumoto & Nishimura, 1998). The RNGs discussed so far are by computational methods. Another approach is by physical methods, e.g., Kanter et al. (2010). The output based on a physical method is usually unpredictable. Thus, this class of random bit generators is commonly known as non-deterministic random bit generators (NRBGs). L'Ecuyer (2010) points out that those physical devices are unnecessary and unpractical for Monte Carlo methods, because deterministic algorithmic methods are much more convenient than hardware devices. See L'Ecuyer (2013) and the numerical algorithms group (2013) for more information on other methods of generating random numbers.

MAIN FOCUS

We discuss the algorithm and implementation of L'Ecuyer's (1999) combined multiple recursive random number generator. A combination of generators can have a much longer period than any of its components. Furthermore, with well-chosen parameters, the CMRG has good structural properties and passes many statistical tests, see Kroese et al. (2011). A list of classical LCGs and their properties can be found on Karl Entacher's website: <http://random.mat.sbg.ac.at/results/karl/server/>.

Basic Generators

A newly employed generator is the combined multiple recursive random number generator, which goes from integer to integer according to the recursion

$$x_{j,n} = (a_{j,1}x_{j,n-1} + \dots + a_{j,k}x_{j,n-k}) \text{MOD } m_j;$$

for $j=1, \dots, J$

$$Z_n = \sum_{j=1}^J (\delta_j x_{j,n}) \text{MOD } m_1$$

$$u_n = \begin{cases} z_n / (m_1 + 1) & \text{if } z_n > 0 \\ m_1 / (m_1 + 1) & \text{if } z_n = 0 \end{cases}$$

where J is the number of MRGs used in the CMRG, j, n, k , and m_j are positive integers, and each $a_{j,k}$ belongs to $Z_m = \{0, 1, \dots, m-1\}$, δ_j are integers, and the greatest common divisor of δ_j and m_j is one for each j . To have fast algorithms, with a given j most $a_{j,k}$ should be 0. The transformation of u_n makes sure that u_n is never equal to 0 or 1 (otherwise, trouble may arise, e.g., when taking the logarithm to generate an exponential random variate). Assume that the m_j are distinct primes and that each recurrence j has a primitive characteristic polynomial, and thus period length $\rho_j = m_j^k - 1$ and the longest possible period for a CMRG is $\rho_1 \dots \rho_J / 2^{J-1}$ (L'Ecuyer, 2013).

The combined generator is a close approximation to a single MRG with a modulus equal to the product of the moduli of the components MRGs. Thus, the CMRG has the advantages associated with a larger modulus while permitting an implementation using smaller values. The CMRG combining multiple recursive sequences provides an efficient way of implementing random-number generators with long periods and good structural properties. If the parameters are well chosen, such generators are statistically far more robust than simple linear congruential generators that fit into a single computer word (L'Ecuyer, 1999).

The Need for Multiple Substreams

Many disjoint random number subsequences are often required in simulation studies, for instance, (1) to make independent replications and/or (2) to

associate distinct “streams” of random numbers with different sources of randomness in the system to facilitate synchronization for variance reduction. To produce such “streams,” different seeds (values of vector S_i) must be obtained far enough apart in the sequence to insure that the streams do not overlap. Selection of seeds should also consider statistical properties between streams, such as apparent independence.

In other words, given any X_i (with seed S_i) and positive integer v , there should be a quick way to compute X_{i+v} (with seed S_{i+v}) without generating all intermediate values. The availability of efficient jump-ahead methods is very useful because it permits one to partition the RNG sequence into long disjoint stream and substreams of random numbers. Most packages offer no facility for jumping ahead directly from X_i to X_{i+v} or to compute distant seeds efficiently. Many simulation languages offer a limited number of streams, all based on the same generator, but using fixed starting seeds set say 100,000 values apart. This provides relatively low flexibility. Suppose, for instance, that you want to perform independent pairs of replications with common random numbers across the configurations (i.e., between any two runs of the same pair) in order to compare two different configurations of a system.

To insure proper synchronization, you want every generator to start from the same seed in both runs of the same pair. However, in general, these two runs will make a different number of calls to a generator, and programming “tricks” should be used to skip a proper amount of random numbers to resynchronize the generators for the next pair without overlap in the random number streams. This requires extra programming effort and could be error prone. Good software tools should ease the programmer’s task in that respect. A simple procedure call should permit resetting a generator to previous seed or jumping ahead to a new seed for the next run. Of course, the sequence of “new seeds” (one per run) should be the same of both configurations for the system. Implementing such tools requires efficient “jumping ahead” facilities,

which in turn ask for efficient procedures to compute $(a \times s \text{ MOD } m)$, where a and s are positive integers.

Computing $(a \times s \text{ MOD } m)$

Consider a 32-bit computer on which all integers between -2^{32-1} and 2^{32-1} (exclusive) are well represented. We want to compute $(a \times s \text{ MOD } m)$, where a , s , and m are positive integers smaller than 2^{32-1} . Without loss of generality, we assume that $a < m$ and $s < m$ (if not, replace a and s by $a \text{ MOD } m$ and $s \text{ MOD } m$, respectively). In order to keep seeds with 32-bit precision, all operations can not produce any number greater than 2^{53} (the IEEE-754 standard, i.e., the floating-point numbers have at least 53 bits of precision for the mantissa). Therefore, special algorithm was needed to compute $(a \times s \text{ MOD } m)$, where a and s are less than 2^{32} (around 4.3×10^9).

The following algorithm was used. Let

$$a = a_1 \times 2^{17} + a_2$$

so

$$a \times s = a_1 \times s \times 2^{17} + a_2 \times s$$

Therefore,

$$a \times s \text{ MOD } m = \left((a_1 \times s \text{ MOD } m) \times 2^{17} + a_2 \times s \right) \text{ MOD } m$$

where $a_1 < 2^{15}$, so $a_1 \times s < 2^{47} (= 2^{15} \times 2^{32})$, and $a_2 < 2^{17}$, so $a_2 \times s < 2^{49} (= 2^{17} \times 2^{32})$. Because $z = (a_1 \times s \text{ MOD } m) < 2^{32}$, we have $z \times 2^{17} < 2^{49}$ so that all the intermediate terms in the above computations are less than 2^{53} . Therefore, all seed values will have exact accuracy.

Note that $(a \times s \text{ MOD } m)$, where a and s are less than 2^{32} , can be computed directly on computers that are capable of performing operations with 128 bit quadruple precision, i.e., numbers as large as 2^{113} (around 1.0×10^{34}).

Computing the Jumping Matrices

The initial state of substreams can be computed easily if jumping-ahead facilities are available for the individual MRG components; that is, if an efficient algorithm is available for computing the state of the MRG v steps ahead of the current one, for large values of v . L'Ecuyer (1990) explained one way of doing that, based on the fact that the MRG can be viewed as a LCG in matrix form, whose state is a k -dimensional vector and whose multiplier is a $k \times k$ matrix A . To jump ahead by v values, just multiply the current state by $(A^v \text{MOD } m)$. The matrix $(A^v \text{MOD } m)$ can be pre-computed in time $O(\log_2 v)$, using the divide-and-conquer algorithm (Knuth, 1997).

That is, for the MRG random number generator, X_{i+v} can be computed directly from X_i using

$$\begin{aligned} X_{i+v} &= (A^v X_i) \text{MOD } m \\ &= (A^v \text{MOD } m) X_i \text{MOD } m \end{aligned}$$

where

$$A = \begin{pmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ a_k & a_{k-1} & \cdots & a_1 \end{pmatrix}$$

is an invertible $k \times k$ matrix and

$$X_i = \begin{pmatrix} X_i \\ X_{i+1} \\ \vdots \\ X_{i+k-1} \end{pmatrix}$$

is a $k \times 1$ vector. When A has this special structure, the first $k-1$ components of X_i are obtained by shifting the last $k-1$ components of X_{i-1} , and the last component of X_i is a linear combination of the components of X_{i-1} , according to the MRG

(L'Ecuyer, 1990). Kroese et al. (2011) point out that an MRG can be interpreted and implemented as a matrix multiplicative congruential generator, i.e.

$$X_i = (A X_{i-1}) \text{MOD } m, i = 1, 2, \dots$$

The divide-and-conquer algorithm (Knuth, 1997) was used to compute the jumping matrices A^v using the following recursion:

$$A^v \text{MOD } m = \begin{cases} A & \text{if } v = 1; \\ A(A^{v-1} \text{MOD } m) \text{MOD } m & \text{if } v > 1, v \text{ odd}; \\ (A^{v/2} \text{MOD } m)(A^{v/2} \text{MOD } m) \text{MOD } m & \text{if } v > 1, v \text{ even} \end{cases}$$

A Random Number Package

We now propose a portable set of utilities for random number generation. We consider a basic underlying generator of period p . Let s_0 be the basic seed (initial state) for this generator and $s_1, s_2, \dots$ be its sequence of successive states. Let T denote the transition function of the generator, that is, the operator $T: S \rightarrow S$ such that $T(s_i) = s_{i+1}$, and T^q its q -fold composition ($T^q(s_i) = s_{i+q}$). Starting from states $I_1 = s_0, I_2 = s_q = T^q(I_1), I_3 = s_{2q} = T^q(I_2), \dots, I_G = s_{(G-1)q} = T^q(I_{G-1})$, respectively. Each of these G sequences corresponds to a “stream”, with length q . Note that q needs to be a very large number, say no smaller than 10^9 . Hence, there will be G virtual RNGs. I_g is called the *initial seed* of stream g . At any moment during program execution, stream g is in some state C_g , say, in its subsequence number r , that is, such that $C_g = T^{r-1}(I_g)$. We call C_g the *current state* of stream g .

The product of $a_{ij}(m_j - 1)$ is less than 2^{53} . If this condition holds, then the integer $a_{ij}x_{ij}$ is always represented exactly in floating point on a 32-bit computer that supports the IEEE floating-point arithmetic standard, with at least 53 bits of precision for the mantissa. The generator can then be

implemented directly in floating-point arithmetic, which is typically faster than an integer arithmetic implementation. On the other hand, with this implementation, the state of the generator is represented over $64k$ J bits, as opposed to $32k$ J bits when the x_{ij} are represented as 32-bit integers.

The mrg32k3a of L'Ecuyer (1999) implemented a CMRG with 2 components ordered 3, whose coefficients satisfy above condition. The moduli and coefficients are $m_1 = 2^{32} - 209 = 4294967087$, $a_{11} = 0$, $a_{12} = 1403580$, $a_{13} = -810728$, $m_2 = 2^{32} - 22853 = 4294944443$, $a_{21} = 527612$, $a_{22} = 0$, $a_{23} = -1370589$. Its period length is $\rho = (m_1^3 - 1) / (m_2^3 - 1) / 2 \approx 2^{191} \approx 3.1 \times 10^{57}$. This implementation set $\delta_1 = -\delta_2 = 1$. The parameters have been chosen so that the period is long, a fast implementation is available, and the generator performs well with respect to the spectral test. The mrg32k3a has been implemented as one of the core random number generators in many simulation packages.

Before this procedure is called for the first time, one must initialize the global variables s_{10} , s_{11} , s_{12} to (exact) non-negative integer values less than m_1 and not all zero, and s_{20} , s_{21} , s_{22} to non-negative integers less than m_2 and not all zero. The vectors (s_{10}, s_{11}, s_{12}) and (s_{20}, s_{21}, s_{22}) are the initial values of $(x_{1,0}, x_{1,1}, x_{1,2})$ and $(x_{2,0}, x_{2,1}, x_{2,2})$, respectively. They constitute the *seed*.

Therefore, in this implementation

$$x_{1,n} = (1403580.0x_{1,n-1} - 1370589.0x_{2,n-3}) \text{ MOD } 4294967087$$

$$x_{2,n} = (527612.0x_{2,n-1} - 1370589.0x_{2,n-3}) \text{ MOD } 4294944443$$

$$Z_n = (x_{1,n} - x_{2,n}) \text{ MOD } 4294967087$$

$$u_n = \begin{cases} z_n / 4294967088 & \text{if } z_n > 0 \\ 4294967087 / 4294967088 & \text{if } z_n = 0 \end{cases}$$

The matrix A_1 for s_{1n} to jump ahead one step is

$$A_1 = \begin{pmatrix} 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 1.0 \\ -810728.0 & 1403580.0 & 0.0 \end{pmatrix}$$

and the matrix A_2 for s_{2n} to jump ahead one step is

$$A_2 = \begin{pmatrix} 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 1.0 \\ -1370589.0 & 0.0 & 527612.0 \end{pmatrix}$$

The List 1 is an implementation of the CMRG (L'Ecuyer's mrg32k3a) in C.

The mrg32k3a RNG software packages are available for download via url <http://www.iro.umontreal.ca/~lecuyer/myftp/streams00/>

Jumping Backward

The jump-back matrix also exists. This is true because each component has a primitive characteristic polynomial (a necessary condition). Given a vector s_n , one may jump back v steps to s_{n-v} . For example, the jump-back-one-step matrix B_j is $A_j^{\rho_j-1} \text{ MOD } m_j$, where ρ_j is the period of the j th MRG of the CMRG. As one might expect, $A_j^v \times B_j^v \text{ MOD } m_j$ turns out to be the identity matrix I , for $v = 1, 2, \dots, \rho_j$. This equation is consistent with our intuition that $A_j^{\rho_j-1} \text{ MOD } m_j = I$, and this follows from Fermat's theorem. The matrix B_j generates the same stream but in reverse order. As we can see from the new recursion below, the values of the parameters b_{ij} are much larger than the original ones, where b_{ij} are the parameters of the new CMRG. Furthermore, we no longer have $b_{ij}(m_j-1) < 2^{53}$ for all b_{ij} . Therefore, the original recursion provides a more efficient generator.

The matrix B_1 for s_{1n} to jump back one step (i.e., jump ahead ρ_1-1 step) is

List 1.

```

#define norm          2.328306549295728e-10          // 1.0/(m1+1)
#define norm2         2.328318825240738e-10          // 1.0/(m2+1)
#define m1            4294967087.0
#define m2            4294944443.0
// the initial seed
double               s[2][3] = {
{0.0,                0.0,                1.0},
{0.0,                0.0,                1.0}
};
double MRG32k3a()
{
long k;
double p;
p = 1403580.0 * s[0][1] - 810728.0 * s[0][0];
k = long (p / m1);      p -= k*m1; if (p < 0.0) p += m1;
s[0][0] = s[0][1]; s[0][1] = s[0][2]; s[0][2] = p;
p = 527612.0 * s[1][2] - 1370589.0 * s[1][0];
k = long (p / m2);      p -= k*m2; if (p < 0.0) p += m2;
s[1][0] = s[1][1]; s[1][1] = s[1][2]; s[1][2] = p;
if (s[0][2] <= s[1][2]) return ((s[0][2] - s[1][2] + m1) * norm);
else return ((s[0][2] - s[1][2]) * norm);
}

```

$$B_1 = \begin{pmatrix} 184888585.0 & 0.0 & 1945170933.0 \\ 1.0 & 0.0 & 0.0 \\ 0.0 & 1.0 & 0.0 \end{pmatrix}$$

$$x_{2,n} = (360363334.0x_{2,n+2} - 4225571728.0x_{2,n+3}) \text{ MOD } 4294944443$$

or

$$x_{2,n} = (360363334.0x_{2,n+2} - 69372715x_{2,n+3}) \text{ MOD } 4294944443$$

and the matrix B_2 for s_{2n} to jump back one step (i.e., jump ahead ρ_2-1 step) is

$$B_2 = \begin{pmatrix} 0.0 & 360363334.0 & 4225571728.0 \\ 1.0 & 0.0 & 1.0 \\ 0.0 & 1.0 & 0.0 \end{pmatrix}$$

The reverse stream follows the recursion

$$x_{1,n} = (184888585.0x_{1,n+1} - 1945170933.0x_{1,n+3}) \text{ MOD } 4294967087$$

Generating Nonuniform Random Variate

To simulate the underlying system under study, various nonuniform random variates are required. These random variates are used to simulate the observations from the desired distribution. Random variates from distributions other than the uniform [0,1] are generated by applying further transformations to the output value u_i of the uniform RNG. The simplest way of generating a random variate X with distribution function F

is using the inverse transformation. Let $U(a,b)$ denote the uniform distribution between a and b . Based on the fact that $y=F(x)\sim U(0,1)$, we generate a random variate $U\sim U(0,1)$ and return the value $X=F^{-1}(U)$ as a variate with distribution F . Here F^{-1} is the inverse distribution function (or quantile function) and is defined by

$$X = F^{-1}(U) = \inf \{x : F(x) \geq U\}.$$

Note that

$$\begin{aligned} P(X \leq x) &= P(F^{-1}(U) \leq x) \\ &= P(U \leq F(x)) = F(x) \end{aligned}$$

For more information of using inverse transform to generate random variates, see Law (2014). Other methods are available when F^{-1} is difficult or expensive to compute, see Kroese et al. (2011).

FUTURE TRENDS

Random number generators continue to be key components of any computer simulation, cryptography, and other areas where producing an unpredictable result is desirable. As computers become 64-bits based operation, RNGs based on 64-bits will be developed. Utilities for RNGs will be incorporated into many simulation packages and will be readily available for simulation practitioners.

CONCLUSION

We have discussed the backbone CMRG random-number generator, several utilities to enhance its practical use, and implementation issues. Our implementation eliminates the need to use a fixed number of pre-computed seeds, which would provide little flexibility. The proposed random-number-generation package provides jumping

facilities, has good speed, a long period length, and excellent theoretical/statistical properties. It provides for multiple generators (streams) running simultaneously, and each generator (stream) has its sequence of numbers partitioned into many long disjoint contiguous substreams. The RNG mrg32k3a has been studied intensively and implemented in several software packages.

KEY TERMS AND DEFINITIONS

Common Random Numbers: A variance reduction technique that uses the same random number streams to simulation different systems.

Deterministic Algorithm: An algorithm that given the same input always products the same outputs.

Deterministic Sequence: A sequence that the value of any future elements can be determined when the value of the current element is known

Jump Ahead (Back) ν Steps: A utility to advance (go back) ν steps in the random number stream without going through the stream sequentially.

Period Length (of RNGs): The length of the random number sequence before it recycles itself.

Quantile Function (Inverse Distribution Function): The quantile function (given a probability p) returns the value at or below which 100 p percent of the population lies.

Random Number Generators (RNGs): Computational or physical devices designed to generate a sequence of numbers that appear to be random, as determined by statistical tests.

Variance Reduction: A technique to reduce the variance of the estimate, hence, increase the precision of the estimate.

A Critical Overview of Image Segmentation Techniques Based on Transition Region

Yu-Jin Zhang

Tsinghua University, China

INTRODUCTION

Image segmentation is the key step from image processing to image analysis, and is an important technique of image engineering (Zhang, 2009). It refers to the general procedures and processes for dividing an image into regions with each has some particular characteristics and extracting the target region of interest. Since there is no general theory for image segmentation itself, yet, the image segmentation has always been in-depth study of attention. A large variations of theories and technologies have been applied to solve the image segmentation problem (Zhang, 2006). According to a study based on EI Compendex, the first segmentation algorithm is proposed in 1962, the number of literatures on image segmentation has reached 77,000 half-century late (Zhang, 2015b). According to the increasing tendency, it is estimated that this number should be around 100,000 now.

Image segmentation based on transition region is a special or distinctive type of techniques that are different from traditional boundary-based or region-based techniques. Its strategy is first detecting a transition region between object regions and background regions, then segmenting image into object region and background region based on the properties of transition region. The first technique using transition region is often referred to effective average gradient (EAG) that in fact is just the name of the core parameter of this technique. EAG has raised more than a quarter of a century ago (Zhang, 1989). Journal paper (Zhang, 1991) introduced this technique in detail,

and journal paper (Zhang, 1996) further extended this technique to more general situations. Since then, there are many subsequent related researches and applications, and a series of papers in the literature citing (Zhang, 1991) and/or (Zhang, 1996) are published worldwide (Zhang, 2015a).

Using Google Scholar, a number of papers citing (Zhang, 1991) and/or (Zhang, 1996) are searched and selected, a study on the statistics of these papers is conducted, an analysis of these papers is performed, and discussions on these results are provided.

BACKGROUND

The main contributions of the original journal papers (Zhang, 1991) and (Zhang, 1996) can be summarized into five points:

1. **They Clarified the Three Evidences for the Existing of Transition Region:** Firstly it can prove that, according to Shannon sampling theorem, the discrete edge obtained by sampling a continuous image has always a transition region of at least one pixel wide (Gerbrands, 1988). Secondly the transition region in the actual image can be directly observed. Finally, the transition region can be generated by means of smoothing property inherent in the nature of image capturing.
2. **They Analyzed the Rationality and Feasibility of Using the Transition Region for Segmentation:** The transition region is spatially located between the object and

the background, so the boundary separating the object and background should be in the transition region. Moreover, the gray-values of transition region are in the middle of the gray-values of object pixels and background pixels, so if the thresholding techniques is used for segmentation, the appropriate threshold values should be belong to the value set of the transition region pixels. In addition, selecting the threshold value from the transition region must be more reliable than selecting the threshold value from the full image.

3. **They Put Forward a Specific Method for Determining the Transition Region:**

Although the existing of transition regions is an objective reality, the effective detection method is required. To determine the transition region in actual images, a method consisting of clip transformation of images, computation of the EAG curves, determination of the optimal dynamic range, and thereby extracting the transition region is proposed. This method converts the problem of determining the transition region into an optimization problem, without any preset parameter to be adjusted in the determination. This fully automatic method has the iterative nature and uses the global information of images, so it is relatively stable and robust. Finally, according to the characteristics of the EAG curve, a fast realization way is designed to improve the computational efficiency.

4. **They Proved Three Properties of the Two Gray-Values Defining the Transition Region:**

Depending on the aforementioned computation method for the transition region, the dynamic range of transition region is defined by two gray-values (i.e., L_{low} and L_{high}) obtained from EAG curve. With the help of mathematical analysis, three properties of these two values are formally proved: 1) They always exist and only one for each transition region; 2) They can make both corresponding functions $EAG(L_{low})$ and

$EAG(L_{high})$ reaching the maximum values; 3) They satisfy $L_{low} < L_{high}$ in practical situations. In (Zhang, 1996), these three properties are also proved for images having more than one transition region.

5. **They Discussed How to Use the Transition Region Further to Segment Image:**

On the basis of the transition region extracted, according to the property that the gray-value range of transition region is between gray-values of object and background, a suitable threshold value can be determined with the help of gray-values of the transition region, for example, this threshold value can be the average value or the mode value of the gray-value ranges of the transition region.

SURVEY ON THE FOLLOW-UP LITERATURE

A large number of follow-up researches for (Zhang, 1991) and/or (Zhang, 1996) have been conducted, many new papers have been published in referring/citing them. With the help of Google Scholar, many of them (most of them are journal papers) can be found.

Citation-Statistics Over the Years

According to the search results from Google Scholar, so far the number of records citing (Zhang, 1991) is 87, the distribution of these records for each year is shown in Figure 1; and the number of records citing (Zhang, 1996) is 59, the distribution of these records for each year is shown in Figure 2.

The total number of records citing these two papers reaches 146. However, after a careful reading and checking of all these records, it is found that 7 of them are incorrectly picked up by Google Scholar (3 records for citing (Zhang, 1991), 4 records for citing (Zhang, 1996)). On the other side, there are 13 records citing both (Zhang, 1991) and (Zhang, 1996). After screening, there are totally 126 papers citing (Zhang, 1991)

Figure 1. The distribution of the 87 records citing (Zhang, 1991) for each year (from Google Scholar)

Figure 2. The distribution of the 59 records citing (Zhang, 1996) for each year (from Google Scholar)

and/or (Zhang, 1996), their distribution is shown in Figure 3. In Figure 3, the red (dark) columns denote the papers citing only (Zhang, 1991), the green (light) columns denote the papers citing only (Zhang, 1996), while the columns with pattern denote the papers citing both (Zhang, 1991) and (Zhang, 1996).

From Figure 3, it is seen that the majority of follow-up papers are published in the past 10 years. For example, there are 42 records in the 5 year's period from 2011 to 2015; there are 41 records in the 5 year's period from 2006 to 2010; while there are only 43 records for the rest 15 years

(before 2004). It seems the related researches for transition region-based image segmentation have an upward trend, though many years have passed since its publication.

Purpose-Statistics Over the Years

From the perspective of scientific researchers, the purposes for paper citations of academic and technical literatures can be attributed mostly to the following three groups.

Figure 3. The distribution of the 126 records citing both (Zhang, 1991) and (Zhang, 1996) for each year

1. **Introduction/Indication:** Citing the paper as the example of a kind of typical techniques, especially in the review articles or in the literature review section of a paper.
2. **Applications:** Using the concepts and/or algorithms presented in the cited paper for a practical work (implementation may be required, and some parameters may often be adjusted to suit specific application needs).
3. **Follow-Up Research:** With the analysis of the principles and/or deficiencies presented in the paper, put forward some new concepts and ways to improve the technical performance, or to modify/extend the technique to a wider range of application fields.

By analyzing the above 126 papers with emphasis on their main purposes, it is found that 29 of them can be classified into the first group, 44 of them can be classified into the second group, while 53 of them can be classified into the third group. It seems that this type of techniques not only be widely applied, but also be grasped by the attention of many researchers. The distributions of these three groups for each year are shown in Figure 4, with the red (dark) columns denoting the first group, the green (light) columns denoting the second group, and the columns with pattern denoting the third group.

Content-Statistics Over the Years

From the point of view of academic and technical research, the 53 papers belong to the third groups are worthy of further analysis.

Firstly, all these papers hold a positive attitude for the existence of the transition region in images, and some of them also provide further refinement or more examples. Most of them also recognized the rationality and feasibility of the transition region for image segmentation. They conducted a number of works for the determination of transition regions as well as for the segmentation of image based on transition regions.

The original methods mentioned in (Zhang, 1991) and (Zhang, 1996) for computing the transition region is relatively simple and intuitive, the follow-up researches started from different angles, and designed different methods for improving the performances, such as the segmentation accuracy and noise robustness. Among these methods, most of them can be described from the consideration of their understanding of the transition region.

To extract the transition region from images, it is necessary to separate the transition region from both object and background regions. This task can be regarded as a classification problem, and suitable features (representing the characteristics of different regions) for classification

Figure 4. The classification of the 126 records into 3 groups according to their citing purposes for each year

are required. One important characteristic of the transition region is the relatively significant gray-level variations in a comparatively small space or scale. It may be caused by two factors, one is the existence of large gray-level difference between adjacent pixels in transition region, and other is the presence of frequent changes of gray-level among neighboring pixels in transition region. Of course, the effects of these two factors may also be conjoined. In other words, the transition regions would be characterized by large variations and/or high frequency of pixel values.

For the 53 papers belong to the third group, most of them still determine the transition region based on these two factors, some papers use one of two factors and several papers combine two factors. There are also certain papers with other particular/specific approaches. So, according to the contents, these papers can be classified into 4 categories:

1. Consider the magnitude change of gray values.
2. Consider the frequency change of gray values.
3. Consider both magnitude and frequency changes in conjunction.
4. Other approaches based on different ideas and focuses.

The distributions of these four categories for each year are shown in Figure 5, with the red (dark) columns denoting the first category, the green (light) columns denoting the second category, the columns with pattern denoting the

third category, and the white columns denoting the fourth category. One thing can be seen from Figure 5 is that most papers in the third category are published recently.

ANALYSIS AND DISCUSSION ON SOME ISSUES

In the follow-up study of the transition region-based image segmentation techniques, there have been some doubtful claims and statements. A number of them have already been announced or discussed in papers (Zhang, 1991) and (Zhang, 1996), but it seems that they have not been noticed or have not been properly understood. Below, some of them raised from the following four citing papers are analyzed and discussed, in order to guide the further works along correct directions.

Paper (Groenewald, 1993)

From the perspective of gradient computation, the paper (Groenewald, 1993) compared the effective average gradient (EAG) method (Zhang, 1991) with the average gradient (AG) method (Watanabe, 1974) and the more general histogram transformation / modification (HT/HM) method (Weszka, 1979). It deduced that EAG is a smoothed version of AG or HT/HM. Moreover, it also designed an example to point out there may be situations with $L_{low} > L_{high}$, and thus to challenge the third property of the two gray-values defining the transition region. However, these claims are questionable.

Figure 5. The classification of the 53 records into 4 categories of contents for each year

First, it must highlight that EAG is not a smoothed version of AG. According to the definition of EAG, where only the pixels with not zero (or very small) values of gradient are considered in the EAG computation, EAG is a selected statistics, and is different from AG. In addition, in order to compute $EAG(L_{low})$ and $EAG(L_{high})$ curves, special clip transformations (cut section will be set to cutting value) in low-end and high-end are introduced respectively, only the pixels retained after the clip transformation are considered in the EAG computation. Both selections are corresponding to non-linear transformations, and the result is a function of clip level (cutting value), so the relation between EAG and AG is absolutely not a simple smooth one. Furthermore, although both EAG and AG make use of the 2-D local contrast information in image, EAG also utilizes 2-D global information in computation. Different from HT/HM that uses each time only the overall information of pixels in one gray value, EAG utilizes each time the overall information of all the pixels with non-zero values of gradient, and thus is more robust to noise. This can also be seen directly from the comparison of Figure 4 and Figure 5 in (Zhang, 1991).

Second, it should point out that the paper (Groenewald, 1993) ignored the pixels with zero gradient value in the simplified approximation to gradient computation. This is equivalent to only take the values of low-end clip and high-end clip as the minimum and maximum values of images, respectively, and does not reflect the dynamic influence caused by the change of clip values. It is seen that, on the one hand the simplification in (Groenewald, 1993) is just a rough approximation to HT/HM; on the other hand the gradient computation in (Zhang, 1991) is not the traditional computation. Considering the common segmentation model that assumes an object on background, then the most of the pixels in the image are either in the internal of object or in the internal of background, the pixels on the border between object and background are only a small part. If one relays the limit of zero gradient as the

approximation did in (Groenewald, 1993), most of the pixels will be ignored in that way, such an approximation is obviously unreasonable.

Finally, the paper (Groenewald, 1993) gives an example to illustrate that the situation of $L_{low} > L_{high}$ might happen, but in fact the example given is just a case that there are two non-overlap transition regions (the corresponding profiles of two transition regions are connected) in a gray value image. If extending the 1-D edge curve from the example of (Groenewald, 1993) whose gradient curve has two pics in 2-D plane, the situation would be as shown in Figure 6, where the first pic would correspond to the transition region 01 between background 0 and object 1, while the second pic would correspond to the transition region 12 between object 1 and object 2. In this case, the object 1 could be seen as the background of object 2. Since there are two transition regions, then the computation of L_{low} and L_{high} should be performed for each pair of them. The results would be L_{low01} and L_{high01} corresponding to transition region 01, and L_{low02} and L_{high02} corresponding to transition region 02. In (Zhang, 1996), it pointed out that the three properties of the two gray-values defining the (single) transition region still valid for the case of multiple transition regions, as shown in Figure 9 of (Zhang, 1996), in which $L_{low01} < L_{high01}$ for the first transition region and $L_{low02} < L_{high02}$ for the second transition region. (Groenewald, 1993) compared L_{low02} with L_{high01} , hence the abnormality appeared. In reality, L_{low02} and L_{high01} are belong to two different transition regions, there is no means to make them into comparison.

Paper (Zhang, 2004)

For calculating the gradient values needed to obtain EAG curves, the paper (Zhang, 2004) designed a procedure to accelerate the computation. The result obtained when using Sobel gradient operator is that the number of multiplications and additions can be reduced to $18/256 \approx 7\%$ of direct computation.

In reality, (Zhang, 1991) already introduced a fast procedure to perform similar computation

Figure 6. The illustration of two transition regions in the image

with the help of Fibonacci sequence, the amount of computation can be reduced to less than 5% of direct computation, and this reduction does not depend on the gradient operators used.

Paper (Liu, 2007)

The paper (Liu, 2007) made a review of transition region-based image segmentation methods proposed before 2007, and considered paper (Weszka, 1979) as the first one to introduce the transition region theory into image segmentation. It seems that this statement does not understand the meaning of transition region and does not distinguish these two methods clearly.

Literally, there has been no term “transition region” appeared in (Weszka, 1979), let alone “transition region theory”. In fact, (Weszka, 1979) discussed the histogram modification / histogram transformation (HM/HT) method, whose basic idea is to rise the difference between the peaks and valleys in the histogram of the original image by using other information than just pixel gray values, so as to increase peak-valley discrimination and to facilitate the selection of threshold from histogram. On the other side, EAG of (Zhang, 1991) and (Zhang, 1996) directly determines the transition region and then the threshold for segmentation, without any histogram computation. Obviously, these two methods are different both in basic ideas and in technical route. They should not be confused.

In (Zhang, 1991), the evaluation and comparison of EAG and HM/HT are already performed. HM/HT takes the edge value of each pixel to weight its role played in the selection of threshold, but does not distinguish the edge values caused by gray value variation among neighboring pixels with that caused by noise. In EAG method, the contribution of each pixel to the selection of threshold does not only depend on the gradient value of that pixel but also depend on the distribution of gray values in the entire image. This is equivalent to incorporate not only the edge values but also the global 2-D information (such as pixel distribution information reflected by clip transformation) into the detection of the transition region. Since EAG method combines more *a priori* knowledge than that of HM/HT method, it is expected to provide better result than that of HM/HT method. In addition, except the quantity of *a priori* knowledge, how to use the knowledge also influences the performance. Both EAG and HM/HT methods utilize the local contrast information (edge value information and gradient information), but the ways are different. HM/HT method uses the local contrast information for each gray level separately, while EAG method uses simultaneously the local contrast information of all pixels with non-zero gradient values. As more samples are used in statistics, the EAG method is more robust to noise influence than HM/HT method (Zhang, 1991).

Incidentally, (Liu, 2007) attributed the method of (Wang, 2005) to the class of mathematical

morphology methods, while in fact, there is no any mention of mathematical morphology in (Wang, 2005). Although (Wang, 2005) does some edge thinning operations by using gray values and gradient values in neighborhood, but does not employ any mathematical morphology procedure.

Paper (Hua, 2008)

The paper (Hua, 2008) used a supervised way to specify both gray values for limiting the dynamic range of the transition region (for the purpose of comparison with the original documents (Zhang, 1991) and (Zhang, 1996), these two values will also be referred to as L_{low} and L_{high}), and performed the following clip transformation (to remain the contributions come from pixels in the range of $[L_{\text{low}}, L_{\text{high}}]$ and to remove the contributions come from pixels outside this range):

$$f_{\text{TR}}(x, y) = \begin{cases} L_{\text{low}} & \text{if } f(x, y) < L_{\text{low}} \\ f(x, y) & \text{if } L_{\text{low}} < f(x, y) < L_{\text{high}} \\ L_{\text{high}} & \text{if } f(x, y) > L_{\text{high}} \end{cases}$$

This transformation has basically the same idea as that of the two clip transformations introduced in the original paper (Zhang, 1991). It can be seen as one formula combined two transformations. It has the same effect as the two transformations if initially fixing the first gray value while changing the second gray value, and then fixing the second gray value while changing the first gray value. Nevertheless, two gray values are fixed together in (Hua, 2008), so the potential benefits of (Zhang, 1991) for iterative computation of optimal values separately were lost.

FURTHER RESEARCH DIRECTIONS

As indicated in Figure 3, it seems the related researches are still ascendant. Below are some directions that would be worth for further research.

1. Why were there so many follow-up research works? One important reason is that the transition region has no unique and quantitative definition, yet. Note in (Zhang, 1991), the transition region is just defined by the computation results. Many researches have been largely carried out along this line of thought in these years. For example, local complexity or local entropy based methods need to determine a threshold value for detecting the transition region. Pixels with local complexity or local entropy values greater than (or less than) the threshold will be assigned to the transition region. Paper (Yan, 2005) attempts to define a general transition region, though it does relax the selection for features representing the properties of transition region, a threshold value is still required to detect the transition region. In other words, using different threshold values will result in different transition region. In addition, the fact that there is no unique and quantitative definition for transition region also causes no ground truth in the method evaluation. Moreover, no suitable test database makes the research results difficult to compare, with a number of uncertainties.
2. As mentioned above, for determining the transition region, most methods use information either on the magnitude variation of gray values or on the frequency variation of gray values. Both of them have their own characteristics, each of them has its own application areas. Combination would be a potential solution, but how to learn from each other needs more in-depth research works.
3. Till now, the related researches are basically concentrated in the direction along the third point indicated in background section. However, there would be some research spaces in the direction along the fifth point. After obtaining the transition region, various characteristics of this region can be used for image segmentation. Firstly, the gradation characteristics can be exploited. The range

of gray values is between that of object and background, so the mean or extreme values of transition region can be used to determine a segmentation threshold (Zhang, 1991). Secondly, the spatial characteristics can be exploited. Since the transition region is a strip-shaped region surrounding the boundary of the object, so it can be refined (e.g., using a medial axis transformation or performing a strike skeleton operation) to obtain the object contour inside it (Zhang, 2001). Further researches on other promising characteristics would be worthwhile.

4. Several follow-up researches classify the transition region based methods into two categories: direct methods (directly compute pixels belong to transition region) and indirect methods (first computing range values, then determining the transition region). With the help of common terms in image segmentation, the former can be regarded as the region-based methods, while the latter can be regarded as the boundary-based methods. It is generally believed that the direct methods obtain the transition region straightly, while the indirect methods have turned a corner. However, the ultimate goal of transition region determination is to segment images into object and background. If a threshold value is needed, for direct methods, determining the threshold should be performed after obtaining the transition region; while for indirect methods, the threshold could be determined directly after obtaining the range values of transition region. In case that the transition region is determined by L_{low} and L_{high} , the threshold can be directly computed from these two values, even the explicit extraction of the transition region becomes unnecessary. Here, it seems that the “direct” and “indirect” just swap each other. What lessons could be learnt from it?

CONCLUSION

A survey for researches and applications on image segmentation based on transition region determination (literature searched with the help of Google Scholar) in these years is conducted. These related papers are sorted first according to the publishing year, and then grouped according to their purposes and contents (with techniques used). Some questionable issues in these papers are pointed out and critically discussed, and several further research directions are indicated and analyzed. The statistics shows that the related researches catch a lot of attention, especially in recent years, so further researches, applications, and improvements will continue.

KEY TERMS AND DEFINITIONS

Clip Transform: One operation performed on the gray values of pixels. Classic clip transform assigns the maximum or minimum gray values to the cutting parts. In transition region determination based image segmentation, a particular clip transform is designed, which assigns the clip values to the cutting parts to avoid the effects caused by too big contrast at cutting edge, and to reduce the influence of various interferences.

Effective Average Gradient (EAG): A special expression for or a particular parameter of the average gradient of images, in which only those pixels with non-zero gradient values are involved in the computation. Since the influence of zero gradient pixels is removed, so it is called “effective”. It is a selective statistics of images, and the basis of transition region determination.

Image: An entity that was captured by some visual systems in looking at the real world and that can be sensed to produce perception. It is a representation, likeness, or imitation of an object or thing, a vivid or graphic description, something introduced to represent something else.

Image Analysis (IA): One of three layers of image engineering, which is concerned with the extraction of information (by meaningful measurements with descriptive parameters) from an image (especially from interesting objects).

Image Engineering (IE): An integrated discipline/subject comprising the study of all the different branches of image and video techniques. As a general term for all image techniques, it could be considered as a broad subject encompassing mathematics, physics, biology, physiology, psychology, electrical engineering, computer science, automation, etc. Its advances are also closely related to the development of telecommunications, biomedical engineering, remote sensing, document processing, industrial applications, *etc.*

Image Segmentation: A process consists of subdividing an image into its constituent parts and extracting these parts of interest (objects) from the image.

Image Techniques: A collection of various branches of techniques for processing (such as acquiring, capturing, sensing, storing, enhancing, filtering, deblurring, inpainting, transforming, coding, transmitting, manipulating, *etc.*) analyzing (such as segmenting, representing, describing, featuring, measuring, classifying, recognizing), and understanding (such as modeling, registering, matching, reconstructing, training, learning, reasoning, interpreting, *etc.*) images.

Thresholding: Thresholding techniques are the most popularly used segmentation techniques. A set of suitable thresholds need to be first determined, and then the image can be segmented by comparing the pixel properties with these thresholds.

Development of Image Engineering in the Last 20 Years

Yu-Jin Zhang

Tsinghua University, China

INTRODUCTION

In recent years, images become more and more an important medium for human beings to observe the information of the real world around. Images can be obtained by using different observing and capturing systems in various forms and manners. The human visual system is just a typical example of an observation system. In its general sense, the word “image” could include all entities that can be visualized by human eyes, such as a still image or picture, a clip of video, as well as animations, cartoons, charts, drawings, graphics, paintings, even also texts and visual patterns, etc. In the early days, images were called pictures. Nowadays, with the progress of information science and society, the term “image” rather than “picture” is generally used because computers store numerical images of a picture or scene.

Image techniques are those techniques that have been invented, designed, implemented, developed, and utilized to treat various types of images for different and specified purposes (Zhang, 2009b). The researches and applications based on images are turned out to be a hot spot in the modern information society. They have attracted more and more attention in recent years with the fast advances of mathematic theories and physical principles, as well as the progress of computer and electronic devices, etc.

Image engineering (IE), an integrated discipline/subject comprising the study of all the different branches of image techniques, which has been formally proposed and defined around 20 years ago (Zhang 1996a; Zhang 1996c) to cover

the whole domain, has been evolved very quickly. Image engineering is now a very broad subject encompassing mathematics, physics, biology, physiology, psychology, electrical engineering, computer science, automation, etc. Its advances are also closely related to the development of telecommunications, biomedical engineering, remote sensing, surveying and mapping, document processing, industrial applications, etc.

Twenty years ago, a bibliography series on IE have been started. With a set of carefully selected journals and a thoroughly reading on the papers published, several hundreds of papers related to IE are chosen each year for further classification and statistical analysis. This work has been made already for consecutive 20 years (Zhang, 1996a; Zhang, 1996b; Zhang, 1997; Zhang, 1998; Zhang, 1999; Zhang, 2000; Zhang, 2001; Zhang, 2002; Zhang, 2003; Zhang, 2004; Zhang, 2005; Zhang, 2006; Zhang, 2007; Zhang, 2008a; Zhang, 2009a; Zhang, 2010; Zhang, 2011; Zhang, 2012; Zhang, 2013; Zhang, 2014a; Zhang, 2015). The last summary of this survey series can be found in (Zhang, 2014b).

The main purpose of this survey work is triple, that is, to capture the up-to-date development of IE, to make available a convenient means of literature searching facility for readers working in related areas, and to supply a useful reference for the editors of journals and potential authors of papers. This series summarize the selected papers for each year, analyzes the distributions of the selected papers from various sources and provides various statistics about the classified papers in each subject group. This paper will present an

overview of this survey series by showing the ideas behind and considerations on this work, as well as the comprehensive statistics obtained from this work. Some insights from it are also discussed.

BACKGROUND

For image engineering that is a new discipline, its scope is first described.

IE, from a perspective more oriented to techniques, could be referred to as the collection of three related and partially overlapped groups of image techniques, that is, Image Processing (IP) techniques (in its narrow sense), Image Analysis (IA) techniques and Image Understanding (IU) techniques. In a structural sense, IP, IA and IU build up three inter-connected layers of IE as shown in Figure 1. Each of them operates on different elements (IP's operand is pixel, IA's operand is object, and IU's operand is symbol) and works with altered semantic levels (from low at IP, via middle at IA, and to high at IU). The three layers follow a progression of increasing abstractness (left up arrow) and of decreasing compactness (right down arrow) from IP to IA to IU.

The techniques covered by IP primarily include the acquisition, representation, compression, enhancement, restoration and reconstruction of images. While IP is concerned with the manipulation of an image to produce another (improved) image, the techniques covered by IA are more concerned with the extraction of information from an image

(especially from the objects in it). Compared to IP that takes an image as input and outputs also images, IA takes also an image as input but outputs data extracted from input. Here, the data can be the measurement results associated with specific image properties or the representative symbols of certain object attributes. Based on IA, IU refers to a body of knowledge used in transforming the data into certain commonly understood descriptions, and for making subsequent decisions and actions according to the interpretation of the image contents.

STATISTICS ON IMAGE ENGINEERING LITERATURES

After many years of development, IE (including IP, IA, and IU) has been greatly progressed. What is the current "picture" of IE? Answering this question is the foremost intention of this survey series. For such a purpose, the selection of suitable reference sources and the classification of selected references according to their contents are two important factors. Also for such a purpose, two statistics made by this survey are illustrated in the following.

Selection of Reference Source

As with any other emerging discipline, a large number of references related to IE have been published worldwide. They appear in books

Figure 1. Three layers of image engineering

(encyclopedia, handbook, monograph, and textbook), citation (secondary literature), conference proceedings, journals (periodicals), newspaper, patents, standard, theses (dissertations), yearbook, etc. The most popular ones are books, conference proceedings, and journals. Each of them has its own characteristics. Considering the fast publishing rate, the conference proceedings would be ranked first, followed by journals and then books. Considering the comprehensiveness, the books would be ranked first, followed by journals and then conference proceedings. Considering the quality, coverage, and regularity (which is important for a yearly survey), journals would be ranked higher than that of conference proceedings and books. Combining all these consideration, journals would be a better choice for such a survey series.

Classification Scheme

The classification scheme used in the bibliography series should reflect the contents of references.

A classification problem can be considered as a problem of partitioning a set into subsets. An appropriate classification of references into groups and/or sub-groups should satisfy the following four conditions:

1. Every reference must be in a group.
2. All groups together could include all references.
3. The references in the same group should have some common properties.
4. The references in different groups should have certain distinguishing properties.

Taking into consideration the above four conditions and the current status of IE development in the field, a complete and compact classification of the theories and techniques of IE is proposed (Zhang, 1996a; Zhang, 1996b), evolved and modified with the progress of domain (Zhang, 2001; Zhang, 2006). The current one is listed in Table 1. As a bibliography series, not only the three

Table 1. Classification scheme of literatures in image engineering

Group	Sub-Group
IP: Image Processing	P1: Image capturing (including camera models and calibration) and storage P2: Image reconstruction from projections or indirect sensing P3: Filtering, transformation, enhancement, restoration, inpainting, quality assessing, <i>etc.</i> P4: Image and/or video coding/decoding and international coding standards P5: Image digital watermarking, forensic, image information hiding, <i>etc.</i> P6: Image processing with multiple-resolutions (super-resolution, decomposition and interpolation, resolution conversion, <i>etc.</i>)
IA: Image Analysis	A1: Image segmentation, detection of edge, corner, interest points, A2: Representation, description, measurement of objects (bi-level image processing) A3: Analysis and feature measurement of color, shape, texture, position, structure, motion, <i>etc.</i> A4: (2-D) object extraction, tracking, discrimination, classification and recognition A5: Human face and organ (biometrics) detection, location, identification, categorization, <i>etc.</i>
IU: Image Understanding	U1: (Sequential, volumetric) image registration, matching and fusion U2: 3-D modeling, representation and real world/scene recovery U3: Image perception, interpretation and reasoning (semantic, expert system, machine learning) U4: Content-based image and video retrieval (in various levels, related annotation) U5: Spatial-temporal technology (high-dimensional motion analysis, 3-D gesture detection, tracking, manners judgment and behavior understanding, <i>etc.</i>)
TA: Technique Applications	T1: System and hardware, fast algorithm implementation T2: Telecommunication, television, web transmission, <i>etc.</i> T3: Documents (texts, digits, symbols) T4: Bio-medical imaging and applications T5: Remote sensing, radar, surveying and mapping T6: Other application areas
SS: Summary and Survey	S1: Cross category summary (combination of image processing / analysis / understanding)

layers of IE are distinguished, the technique application is also to be discriminated. In addition, the survey articles should belong to an impartial group. Consequently, this scheme classifies the literatures in image engineering firstly into five groups and further into 23 sub-groups. It is easy to verify that the above four conditions are fulfilled by this classification scheme.

Summary Over Years

The first statistic made from this survey series is a summary of the number of publications in the last twenty years, and also the classification of IE publications in each group, as shown in Table 2.

In Table 2, the total number of papers published in the selected journals (#T), the number of papers

selected for survey as they are related to IE (#S), and the selection ratio (SR), which equals to #S / #T, for each year have been provided. In addition, the paper numbers for five groups (and their percentages in the year) are also listed.

Some interesting points can be noted from Table 2:

1. This work has attended a quite large scale, with nearly 50500 papers involved and more than 12000 papers selected and classified (more than 50 papers per month).
2. IE is an (more and more) important topic for electronic engineering, computer science and automation. The average SR is more than 1/5 (it is more than 1/4 in several recent years),

Table 2. Summary over the last twenty years

Year	#T	#S	SR	IP	IA	IU	TA	Survey
1995	997	147	14.74	36(24.5%)	51(34.7%)	14(9.52%)	46(31.3%)	0
1996	1205	212	17.59	52(24.5%)	72(34.0%)	30(14.2%)	55(25.9%)	3(1.42%)
1997	1438	280	19.47	104(37.1%)	76(27.1%)	36(12.9%)	60(21.4%)	4(1.43%)
1998	1477	306	20.72	108(35.3%)	96(31.4%)	28(9.15%)	71(23.2%)	3(0.98%)
1999	2048	388	18.95	132(34.0%)	137(35.3%)	42(10.8%)	73(18.8%)	4(1.03%)
2000	2117	464	21.92	165(35.6%)	122(26.3%)	68(14.7%)	103(22.2%)	6(1.29%)
2001	2297	481	20.94	161(33.5%)	123(25.6%)	78(16.2%)	115(23.9%)	4(0.83%)
2002	2426	545	22.46	178(32.7%)	150(27.5%)	77(14.3%)	135(24.8%)	5(0.92%)

Total	50478	12126	—	3923 (32.35)	3725 (30.72)	1802 (14.86)	2576 (21.24)	100 (0.83)
Average	2524	606	24.02	196	186	90	129	5

which is remarkable in considering the wide coverage of these journals.

3. IE publication evolves quite steadily. From Table 2, #S has been increased a lot these year. For example, its value in 2009 has attended near 7 times bigger compared to that in the starting year (while the #T in the same year is only 3.6 times bigger compared to that in the starting year). It is clear that the literature for IE evolves fast than other disciple/subjects covered in these journals.
4. The growing rates of publications for IP, IA, IU and TA are different. To make it clear, Figure 2 shows the numbers of publications for these four groups graphically. The four curves in Figure 2 run quite smoothly and have not intercrossed in last seven years (becoming stable), with the rank from top to bottom: IA, IP, TA and IU.
5. The number of publications for IP and IA constitute near 2/3 of the total number of IE publications. This shows that the current research focus of IE are on IA and IP. In contrast, research work on IU needs to be promoted.

Detailed Statistics on Sub-Groups

The second statistic is a detailed classification of IE publications in each sub-group and for each year. The results are listed in Table 3.

Many types of information could be obtained from Table 3; however, only three important observations are pointed out here:

1. From the number of publications in different sub-groups, the top five sub-groups are image segmentation and edge detection (A1), various typical processing techniques (P3), object extraction and recognition (A4), image registration, matching and fusion (U1), and image compression (P4). They are the most important research topics in all these years. However, their development tendencies are different. Since there is no general theory on image segmentation, the research in this sub-group always attracts many attentions, so the number of A1 is continuous rising. On the other side, P4 is continuous declining as researches become matured, just as predicted in (Zhang 2008b).

Figure 2. Number variation of the first four groups of IE literatures in selected publications for last twenty years

Table 3. Detailed classification of IE publications in sub-groups over the last twenty years

Year	P1	P2	P3	P4	P5	P6	A1	A2	A3	A4	A5	U1	U2	U3	U4	U5	T1	T2	T3	T4	T5	T6	S1

Summary	633	356	1146	929	662	197	1410	250	326	966	773	933	262	90	393	124	393	336	237	442	813	355	100

Figure 3. Numbers of publications per year for different sub-group

- Listing the top ranking in each group could also reveal the current research focus. In IP, P3 and P4 are ranked in the top. In IA, except A1, A4 has also obtained a high score. These two sub-groups are closely related in the sense of object detection with object model, the difference is that the former is more like an un-supervised task and the latter is more supervised. Some connections existed between the top one in IU, U1, and the top one in TA, T5. They are both related to remote sensing, the difference is that the former is more focused on theoretical aspects while the latter is more concentrated on application aspects
- Finally, most of the summary in Table 3 are made for all twenty years. However, some sub-groups have only been added to survey in recent years, along the techniques covered appearing with the evolution. Considering this factor, the average numbers of publications per year for different sub-group are supplied in a histogram form in Figure 3. Compared to Table 3, P5 and A5 provide another two promising recent research directions.

A COMPARISON OF FOUR PERIODS OF “FIVE-YEARS”

This survey series started since 1995, and has lasted already 20 years. These 20 years can be divided into four periods of “five-years”. The summary information of selecting image engineering literatures for these four periods of “five-years” are given in Table 4, from column 2 to column 5, respectively. Moreover, the total aggregate data and annual average data for these 20-years are also provided separately in column 6 and column 7. To compare and comprehend trends conveniently, the ratio of second “five-years” over first “five-years”, the ratio of third “five-years” over second “five-years”, and the ratio of fourth “five-years” over third “five-years”, are also computed as listed in column 8 to column 10, respectively. In which, the ratio bigger than 1 represents an increasing development, and the ratio smaller than 1 represents a decreasing development.

The discussions for each line of Table 4 are as follows:

- The total numbers of papers in the first three periods of “five-years” are increasing gradually, but a slight decrease is appearing in the last period of “five-years”. In recent years, the length of many papers are increased, the volume of journal issue is thus relatively reduced.

Table 4. Statistics of four “five-years” selections for publications of image engineering

	First “Five- Years”	Second “Five- Years”	Third “Five- Years”	Fourth “Five- Years”	Sum Over 20 Years	Average Per Year	Second / First	Third / Second	Fourth / Third
# of Total Publications	7165	11654	16022	15637	50478	2524	1.63	1.37	0.98
# of Selected Publications	1333	2699	4185	3909	12126	606	2.03	1.55	0.93
Selection Ratio (%)	18.60	23.16	26.12	25.00	24.02	24.02	1.24	1.13	0.96

- The numbers of selected papers in the first three periods of “five-years” are also increasing gradually, and similarly a slight decrease is appearing in the last period of “five-years”. Apparently, image engineering entered a relatively stable period of development.
- The selection ratios in the first three periods of “five-years” are equally increasing gradually, with a slight decreasing in the last period of “five-years”. The interpretation should be substantially the same as (2).

In order to be more intuitive and clear, Figure 4 to Figure 7 give the classification and comparison of the numbers of papers in 22 sub-groups (except E1) for these four periods of “five-years”. Figure 4 to Figure 7 correspond to groups P, A, U, T, respectively.

In Figure 4 to Figure 7, each bar represents the sum of the five-years, so the analysis for the variations and trends should be more reliable and credible. From the viewpoint of individual technologies, the following points should be noted:

From the viewpoint of individual technologies, the following points should be noted:

- Among the 17 sub-groups began from the first year (existed 20 years ago), four cases can be distinguished. There are six sub-groups with statistical data increasing every stage. They are P1, P3, A1, A4, U3, and T5. These research directions are still rising and expanding in depth and breadth. There are eight sub-groups with statistical data decreasing in one stage. They are P2, A3, U1, U2, T1, T2, T4 and T6. Do these fluctuations

Figure 4. Comparison of the numbers of publications of group P for different techniques in four periods of “five-year”

Figure 5. Comparison of the numbers of publications of group A for different techniques in four periods of “five-year”

Figure 6. Comparison of the numbers of publications of group U for different techniques in four periods of “five-year”

Figure 7. Comparison of the numbers of publications of group T for different techniques in four periods of “five-year”

indeed reflecting the rise and fall of the corresponding research directions? More time is needed to make judgment. There are two sub-groups with statistical data decreasing in two stages. They are P4 and T3. These research directions are relatively matured and widely applied, so the gradual reduction of new researches and results is expected. There is one sub-groups with statistical data decreasing in all three stages. This is A2. It may be disappear in the future.

2. Among the 3 sub-groups began from the second period of “five-years”, sub-group A5 maintained continuously increasing in two stages, and the absolute numbers have been kept at a high level. The other 2 sub-groups are P5 and U4. They are increasing in the second stage and decreasing in the third stage. Considering the coverage of research domain, sub-group A5 should maintain the vitality of a period of time; sub-group P5 may be leveling off; sub-group T4 should have some research space in theory and have to be pioneered in the applications.
3. Among the 2 sub-groups began from the third period of “five-years”, sub-group P6 is increased slightly and sub-group U5 is decreased slightly. As they are relatively new, related researches are still deepening, so it needs to be judged according to the development trend of the future situation.

FURTHER RESEARCH DIRECTIONS

It could be predicted that, from a research point of view, the IE research has a tendency that is going from low level to high level, that is, from image processing to image understanding, via image analysis. As shown in Figure 2, after a chaos in the beginning, Image Processing publications went to top in the early years, and now the Image Analysis overpasses it for several years. It

is expected that more research and application requirements would make Image Understanding goes up fast in near future.

The field of IE has changed enormously in recent years. Many techniques have been developed, exploited or applied only in this century. It is seen that techniques for IE being implemented and used on a scale few would have predicted a few years ago. It is also likely that these techniques will find many new applications in the future.

Viewing the prospective of IE, the work for survey on IE could also be pushed deeply, at least, in two ways. First, since this survey provides an up-to-date picture regarding IE and its research advance, so further research could be advanced and promoted in appropriate directions. Second, according to the principles and methods of bibliometrics, a systematic investigation of the factors of the articles indexed in the survey series could be made.

CONCLUDING REMARKS

This chapter shows an overview of a survey series on IE made in the last twenty years. The idea behind this survey, as well as a thorough summary of obtained statistics for this survey series are illustrated and discussed. All these provide much of useful information regarding the tendency of fast progresses of IE in China and worldwide. On view of the helpfulness of this series for the research community, the 21st and 22nd in this series have also been made (Zhang, 2016; Zhang 2017).

Such a work not only provides a convenient means for literature searching in IE, but also presents a detailed picture of hot research topics in the field. Moreover, it may be useful for publishers who want to quickly capture the general trends of development in IE, and for potential authors who wish to disseminate widely their research results in the associated communities.

ACKNOWLEDGMENT

This work has been supported by the National Natural Science Foundation under Grants NNSF-61171118 and the Ministry of Education under Grants SRFDP-20110002110057.

KEY TERMS AND DEFINITIONS

Bibliometrics: Bibliometrics is a branch of science. It is a type of research method used in library and information science. It utilizes quantitative analysis and statistics to describe patterns of publication within a given field or body of literature.

Image: An entity that was captured by some visual systems in looking at the real world and that can be sensed to produce perception. It is a representation, likeness, or imitation of an object or thing, a vivid or graphic description, something introduced to represent something else.

Image Analysis (IA): One of three layers of image engineering, which is concerned with the extraction of information (by meaningful measurements with descriptive parameters) from an image (especially from interesting objects).

Image Engineering (IE): An integrated discipline/subject comprising the study of all the different branches of image and video techniques. As a general term for all image techniques, it could be considered as a broad subject encompassing mathematics, physics, biology, physiology, psychology, electrical engineering, computer science, automation, etc. Its advances are also closely related to the development of telecommunications, biomedical engineering, remote sensing, document processing, industrial applications, etc.

Image Processing (IP): One of three layers of image engineering, which encompasses processes whose inputs and outputs are both images, with outputs are improved version of inputs.

Image Techniques: A collection of various branches of techniques for processing (such as acquiring, capturing, sensing, storing, enhancing, filtering, deblurring, inpainting, transforming, coding, transmitting, manipulating, etc.) analyzing (such as segmenting, representing, describing, featuring, measuring, classifying, recognizing), and understanding (such as modeling, registering, matching, reconstructing, training, learning, reasoning, interpreting, etc.) images.

Image Understanding (IU): One of three layers of image engineering, which transforms data extracted from images into certain commonly understood descriptions, and makes subsequent decisions and actions according to the interpretation of the images.

INTRODUCTION

The fluidization technology has been closely related to traditional processes, such as petrochemical, pharmaceutical, polymer, food, and incineration (Kunii & Levenspiel, 1991). In these processes, the characterization of solid particles is vital to obtain higher efficiencies and lower process costs. Recently, many clean energy processes (e.g.: mechanical processes, pyrolysis, combustion, and gasification) involving biomass (non-woody and woody plants, and organic wastes) need fundamental parameters to understand energy conversion (physical, chemical, thermal and biological) in obtaining bio-fuels (gas, liquid or solid), electricity or heat. All of them require versatility in a wide range of chemical reactor configurations and designs (Cui & Grace, 2007; Dai & Grace, 2011; Tannous e Lourenço, 2015).

Fundamental parameters are necessary to understand the dynamic behavior of solids in these reactors because the particles have irregular non-spherical shapes. According to Guo, Chen, and Liu (2012), biomass particles are extremely irregular due to their high contents of cellulose, hemicellulose and lignin. Mandø and Rosendahl (2010), and also, Tannous, Lam, Sokhansanj, and Grace (2013) reviewed fundamental definitions for solid particles such as mean diameter and shape.

Different definitions have been presented in the literature to calculate shape factors of solid particles based on two-dimensional (2D) and three-dimensional (3D) analyses. Depending on

the shape, two-dimension representations may be insufficient to represent the true particle shapes (Zavala, 2012; Rodriguez, Edeskär, & Knutsson, 2013; Tannous, Lam, Sokhansanj, & Grace, 2013). The geometry of biomass particles is complex because it depends of the type of raw material and process applied changing its size and shape from the beginning to the end of the process (Dai & Grace, 2011). There is a need to develop appropriate geometrical definitions as well as algorithms to describe particles shapes (Rodriguez, Johansson, & Edeskär, 2012).

This chapter will discuss new software, Particles and Geometric Shapes Analyzer (APOGEO) aiming the determination of major and minor axes, aspect ratio and sphericity of solid particles (mainly biomass) for four different definitions by image processing without any manual work. This software was developed to reach users from academy and industry.

BACKGROUND

The influence of biomass particle shapes cannot be ignored in particle transportation, mixing and fluidization processes. Various particle shapes result in different particle surface areas, in which are heat and mass transfer processes (Guo et al., 2012). Rodriguez et al. (2013) have presented a review about different methods and techniques to determine the geometrical shape of the particles. The authors observed that there is no agreement

on the usage of the descriptors and is not clear which descriptor is the best. A large scale shape classification has been a problem. In addition, the authors considered that image analysis is a promising tool; it presents advantages like low time consumption or repeatability.

When non-spherical solid particles are observed through a microscope, various methods can be used for their sizing, resulting in terms of an equivalent spherical particle. Projected images in microscopes (optical, scanning and transmission) are in two-dimensional and depend on the orientation of the particles (Turbitt-Daoust, Alliet, Kaye, & Matchett, 2000). Particles in a stable orientation tend to have a maximum area causing microscopic measurements larger values than those presented by other methods, i.e., when smaller particle sizes are discarded.

This technique requires the analysis of a number of particles statistically significant, which has needed the use of automatic image analysis programs, conducted with the aid of computers and specific software. This process includes several steps: 1) acquisition and image scanning, 2) pre- and post-processing of the scanned image, 3) measurements (shape, size and count), 4) analysis and data presentation (Papini, 2003).

Currently, different equipments can be found on the market, but a few of them can be use for biomass particles, for example: Olympus BX51 from Olympus Corporation; Morphologi G3 and Sysmex FPA3000 from Malvern Instruments Ltd; Camsizer and Camsizer XT from Retsch Technology GmbH; CILAS granulometer and expert Shape from Compagnie Industrielle des Lasers; Nikon E200 and ImageJ software, DOMAS Digital Imaging System from Fiber and Particle Engineering Laboratory (University of Oulu), and Eyecon™ from Innopharma Labs. These equipments calculate, in general, the aspect ratio, the roundness, the convexity, the elongation, and the linearity of the materials. Remarking that, the quality of the results is dependent on the skill and experience of the operator, and also the correct calibration of the microscope.

In view of the impossibility of obtain such equipments for economic reasons, in 2011, Tannous and Silva (2012) have decided to seek alternatives to solve many research problems concerning biomass particles through of development of their own software to obtain the shape and sphericity of these kind of particles. This laboratory has experience in educational software development (Rimoli, Assis, & Tannous, 2006; Maranesi & Tannous, 2009; Tannous & Rocha, 2012; Tannous & Santos, 2012).

DEVELOPMENT OF APOGEO® SOFTWARE

General Information

APOGEO® (Particles and Geometric Shapes Analyzer) software was developed to reach professionals in different area of expertise (e.g: chemist; physicist; and chemical, mechanical and food engineers). It is based on image processing technique in order to transform pixels in computational objects. This software was published in the National Institute of Industrial Property-Brazil (n° 13085-6) by Tannous and Silva (2012).

The software can quantify the major and minor axes correlating two or three dimensions of particles (e.g.: woods, coconut fiber, sugarcane bagasse, and rice husk) to obtain its sphericity. The particles can be associated with different geometries such as: rectangular parallelepiped, cylinder, oblate and prolate spheroids, and irregular. The results are presented in histograms and tables, but also can be saved in a spreadsheet (Excel file, OpenOffice Calc file).

Minimum Hardware Requirements

APOGEO was developed on personal computer sufficiently supplied with memory and processing of operational systems. The hardware chosen was a processor of 800 MHz, 1 GB of RAM memory, monitor of 15", mouse, keyboard, and Java Runtime Environment (version 1.6.0 or higher).

Methodology Applied

Particle Selection and Recognition

The development of APOGEO software for mapping images requires that it be able to manage with clustering and pattern recognition. Furthermore, it has to manage with both filters to improve image quality, ensuring a valid background and also the impurities on the image plane. According to Starck, Murtagh, and Fadili (2010), the technique of sparse matrices is an efficient solution to solve these problems. This approach is widely used to identify the size and shape of minerals through images by microscopy.

Therefore, using this mathematical technique, it became possible to approach our research of pattern recognition as a problem of sparse matrix assembly. After that, the new task was to transform these sparse matrix computational objects in an easy access and of the manipulation. One solution was found using the recommendation by Cormen, Leiserson, Rivest, and Stein (2002), concerning on the isolation of particles, and saving them into data structures.

The results of this technique were satisfactory, since that became easy to manipulate the data. In terms of development, the software program was simplified allowing the reuse of the data for later processing such as filtering impurities, manually delete particles, and adjusting of the contrast level with the background image.

Image Processing

The result obtained from the image processing should be a group of particles expressed by a set of linked data structures (linked list). However, the transformation of an image into a set of particles is not an elementary task. Various approaches were used in order to avoid memory bottlenecks that would risk the program functionality. Moreover, complex libraries for image processing could not be applied here, because in some of them the portability requirement of the software would be

impaired. In other cases, they would have a considerable increase in the space in disk occupied.

The solution was to use a very simple technique (Cormen et al., 2002), the recurrence or recursion models. The application of this model was given by route taken in account the map of a particle. Once the user find a pixel of a potential particle, one must go through this whole neighborhood, without losing the referential. This approach is called backtracking (McAllister, 2009).

However, it presents a downside of consuming a lot of memory and processing, since the use of recursive functions in programming creates a memory overhead, leading to a stack overflow, which would risk the usability of software. Thus, the maximum image size would be 100x100 pixels, because there could be damaging to the operating system.

In order to enhance the software quality (APOGEO) and overcome its limitation, it was adopted a solution proposed by Abelson, Sussman, and Sussman (1996), which is the replacement of the recursive function model by a data structure called stack. Using this approach, the image processing time reduced more than 10 times, and reduced the file sizes with a maximum of 3200x3200 pixels.

Development Stages

Once defined the approaches for image processing and data storage, the software APOGEO was created considering different steps, such as: image processing, interaction with the end user, and statistical data analysis. Although they are quite distinct in terms of programming approaches, the use of a simplified model of classes by standard Singleton design enabled the interconnection between the three different demands. The use of this model (Gamma, Helm, Johnson, & Vlissides, 1994) led the project in a simplified pattern resulting in class diagram, as shown in Figure 1.

The initial stage of the program consisted in transforming the original image into a binary matrix. The determination of the values, zero (background) and one (potential solid particle),

Figure 1. Class diagram

was made through the comparison between the sum of the scales of each RGB pixel with a pre-defined value named contrast level. After that, with the binary matrix already established, its transformation in a particle group was defined through the flow diagram (Figure 2).

User Interface

The software interface construction was conducted using the Java Swing libraries and Java AWT, which are the libraries for building of Java Graphic User Interface (GUI). Through its simple and standard model becomes possible to construct similar functional interfaces on any operating system.

The APOGEO software was created using NetBeans software (version 6.9.1). It provides a framework for generation of Swing and AWT interfaces. Thus, the effort to generate production code for the graphical interface has been replaced by a dedicated work to create a more intuitive interface, which would provide a better user experience.

Once the graphical development tools were properly chosen, the final design consisted in exploring three scenarios:

1. A panel of image processing, consisting of the original and processed images, and tabs to change the contrast level, excluding impurities, and actual particle sizes;
2. A panel for selecting particles and equations, in which the user could actively interfere in the processes image by excluding some of those particles, and allowing the choice of the desired equations;
3. Statistical information, consisting of histograms, and other statistical data (mean, median, and standard deviation).

A problem inherent in the construction of these interfaces was the use of space to create a rich interface, simple and objective. Based on this, the software APOGEO has four main frames, side frames, and informational messages, in order to assist the user in different stages of the program.

Despite the reservations made to the AWT and Swing interfaces, they are still heavy in terms of processing, but even quite simple. In other words,

Figure 2. Program flow

with the basic modules applied (Java Swing for Java AWT), if the user wants to create a more complex interface or even a graphical effects as transparency and fade, it becomes a difficult task since the framework does not provide a WSIWYG tool. The solution for using more complex libraries creates platform dependencies, which in turn hamper the portability of the software. Figure 3 shows the diagram which the user interacts with the APOGEO interface.

Testing and Reliability

According to Sommerville (2007), the software testing is as important as the software development, once it delivers to the end user one software with quality, avoiding usability, and coherence problems. Following the methodologies suggested by this author, the APOGEO software had two stages of quality assurance: unit and integration tests.

Figure 3. User interface design

Unit Tests

In order to test the program, the JUnit framework was used for some methods and classes. The Unit tests were applied for each empirical equation, in which every result was compared against the others of the adopted references. Moreover, for each routine of image processing there were several comparative tests. Although the computer measurements were executed in few seconds, the manual measurements take a long time to perform, once it had to be made using Technical Standardization. These standards involve several measurements with predefined instruments, such as pachymeter and micrometer.

Integration Tests

Once the unit tests have already concluded, the next step was to integrate both functional methods and the user interface in order to lead a final

product. In this step, some of the interface methods were tested, as well as all equations with different combinations.

We also tested the program walkthrough in order to evaluate the help messages, errors treatment, histograms, and final results. We have also used it in the laboratory in order to evaluate the software performance and usability in research activities.

RESULTS AND DISCUSSION

Opening and Image Processing

The initial frame (Figure 4) shows the menu of image processing along with control buttons considering three parts: customize image, background and number of particles, and file properties. The buttons were placed in order to facilitate the user, in a just one run, to learn how to setup the entire

Figure 4. Program interface: Digital image capture and processing

environment before taking the measurements, without reading the manual over and over.

- The first step of the program is the opening image file. In order to improve the program functioning, the image should be in JPEG format and lower than 3200x3200 pixels. It is noteworthy that the larger the image, the longer will take its processing.
- The second step is the image processing. First of all, the user should choose the background image. If the particle is dark and the background is light in color, we adopt the choice WHITE, otherwise BLACK (default). Once the user has processed the image, it is possible to adjust the contrast level in order to obtain better results in comparison with the first image processing.
- The third step is to choose the particle size. In order to get the correct size, the user must have at least one reference object such as a coin. Because the user knows its dimensions, sets the maximum length of particle looking at the referenced object. By clicking in OK, the user confirms the operation.
- The fourth step is not required, but it is useful if the user wants to filter small particles or powder, that could influence the final results. Adjusting the minimum size, the user can remove powder or small particles from his sample.
- Taking into account the number of particles is very important because the particle images could be overlapping other particles compromising the final results. After following all these steps, click NEXT button.

If the procedure order is not followed, a warning window will appear indicating what details are missing.

Editing Image

The second frame (Figure 5) allows visualizing the reading process results together with the table data (box aside) to the processed image, removing undesired particles, choosing the particle geometry and equations for sphericity calculation, which are based on four references (authors) from the literature.

Waste Removal

The users could also delete the particle in this frame, in order to avoid particles on the screen. To remove them, just select it in the created list and click DELETE PARTICLE or press DELETE on the user keyboard. A warning will appear indicating which particle has been deleted. To check the result, just click on the underlying or adjacent element of the list.

The Choice of Particle Geometry and Equation

There are five different options of geometry in this software: cylindrical, oblate spheroid, prolate spheroid, rectangular parallelepiped and irregular. The geometries were associated with food and biomass particles (Figure 6) such as: (a) coconut fiber and sugarcane bagasse, (b) lentil, (c) rice husk, (d) Brazilian woods, (e) Hedgehog Brazil nut.

Four definitions are referenced in the software considering two (2D) and three dimensions (3D) of particles according to the traditional literature of fluidization technology: Wadell (1935), Riley (1941), Curray (1951) and Massarani and Peçanha (1986). The software measures two particle dimensions (A and B). To calculate the sphericity in three distinct dimensions of particles (e.g.: oblate and prolate spheroid, and rectangular parallelepiped), it is necessary to assign the value represented by the letter C (Figure 6). The user can choose two paths to introduce this value in the software: (1) measuring the third dimension of the sample by experimental work (e.g: 100 particles) (Farias,

Figure 5. Program interface: Editing image

Figure 6. Particle geometry

2012; Lourenço, 2012) or (2) adopting the value suggested in the software, clicking on the button “3D” (choice of third dimension). After choosing the desired definition, just click on the NEXT button which displays a frame containing the data distribution in histograms.

Histograms

The third frame (Figure 7) provides a graphic display of histograms which allows a better perception over the distribution of measurements. The relative data distributions were concerning to the minor and major particles axes, aspect ratio

(L/D) and sphericity considering 2D or 3D. The histograms allowed for identifying which particle are out of expected results, and then, the users could delete these particles in order to get better results in their experimental analysis.

Besides that, a help menu was created to aid the users in case the misunderstanding of representations.

Final Results

The fourth and final frames (Figure 8) show the overall statistics for each measurement (major and minor axes, aspect ratio and sphericity) accord-

Figure 7. Program interface: Histograms

ing to their minimum, maximum, mean, median and standard deviation. Three significant digits were considered, due to the uncertainty of the conversion of pixel to millimeters. Furthermore, in this frame the user could SAVE THE DATA in a spreadsheet (Excel file, OpenOffice Calc file), where it could use them anytime and anywhere. Saving the data, the users should insert the file and folder names.

The navigation through these four frames is simple and it is not necessary to reprocess the image. The user can back and forward whenever one wants, because the information is stored in the memory during software execution. There is no database embedded on this software, but the results can be saved in a spreadsheet as Microsoft Excel or OpenOffice Calc.

The software APOGEO has a great advantage over possible competitors: a platform independent approach. In comparison with other similar software, such as ImageJ and some modules of

Matlab, its small space demanded for storage, language (Java) and portability are very attractive in favor for using.

Currently, our software has played a fundamental part in the conduct of research on biomass, because with automated measures implied by the program, the time for quantification and measurement of the particles decreased from hours to less than 1 minute. Without modifying its structure, it could contribute to the industry, automating systems and being able to choose particles or objects to any process. The disadvantage of the software is the lack of efficient algorithms for image processing, which would allow large files at high resolutions.

FUTURE RESEARCH DIRECTIONS

For future works, some new features will be implemented in the software, such as: increasing

Figure 8. Program interface: Final results

The screenshot shows a software window titled 'Final Results' with a menu bar containing 'File', 'Print', and 'Help'. The main area is divided into four quadrants, each displaying statistical data for a specific particle property. Each quadrant has a title and five rows of data, each with a label and a text input field containing a numerical value.

Length		Width	
Mean (mm)	2,226	Mean (mm)	0,264
Std. Deviation	0,698	Std. Deviation	0,066
Median (mm)	2,054	Median (mm)	0,258
Minimum (mm)	1,359	Minimum (mm)	0,129
Maximum (mm)	5,000	Maximum (mm)	0,533

Aspect Ratio		Sphericity	
Mean (mm)	0,126	Mean (mm)	0,349
Std. Deviation	0,040	Std. Deviation	0,055
Median (mm)	0,125	Median (mm)	0,352
Minimum (mm)	0,047	Minimum (mm)	0,218
Maximum (mm)	0,248	Maximum (mm)	0,490

Below the data tables, there is a button labeled 'Save in a Datasheet'. At the bottom of the window, there are two buttons: 'Back' and 'Next'.

the image size (higher than 3200 pixels) in order to read high-definition images; new filters can be applied in order to improve the image quality, and the software performance; choosing the particle that will be deleted by clicking over it, instead of navigating through each particle in order to find it; applying of the APOGEO software in a web service available for several platforms; and the software could be used as a pattern recognition software.

CONCLUSION

The software APOGEO was created to overcome the need for a automation tool of size and shape of solid particles (mainly biomass) measurements in a consistent and efficient manner. The computational methodology allowed the construction of a robust and simplified program. Furthermore, the alliance between the computational expertise and technical knowledge in particle analysis was es-

sential for determining their functions, equations, as well as its user interface. The validation of the results and the establishment of limits for its use were performed using a detailed analytical study. In a comparative analysis, APOGEO has proved to be very efficient compared to its competitors, but moreover, it also has the advantage of being portable to different operating systems, and have minimum requisites compatible to the most current devices. The field of applications and future improvements of the APOGEO is quite promising, leading to a wide range for its use, in academy or industry.

ACKNOWLEDGMENT

The authors would like to thank the contribution of students of Laboratory of Particle Technology and Multiphase Processes, School of Chemical Engineering at University of Campinas.

KEY TERMS AND DEFINITIONS

Data Structure: A particular way of storing information, allowing to a high level approach on the software implementation.

Fluidized Bed: Technology related to the fine and large solids transforming into a fluid-like state through contact with a gas or liquid.

Graphical Interface: The interface between a human and a computer through windows, symbols and images.

Image Processing: A computer technique which process a two dimensional picture.

Object-Oriented Programming: A programming paradigm that uses “objects” and their interactions to design applications and computer programs.

Particle Sphericity: The description of the overall shape of the particle irrespective of angularity of edges and corners.

Recurrence or Recursion: A function or method that replicates itself into entries until reach the base case.

C

The Understanding of Spatial–Temporal Behaviors

Yu-Jin Zhang

Tsinghua University, China

INTRODUCTION

The human visual process can be seen as a complex process ranging from feeling (feel the projection of 3-D world on the resulting 2-D image) to perception (capturing the content and meaning of 3-D world with 2-D images) (Kong, 2002). The ultimate goal of vision, from the narrow sense, is to make a meaningful interpretation of the world and the description of the scene; while broadly speaking, it includes also designing a behavior plan based on these explanations and descriptions, and in accordance with the surroundings and wishes of viewers. Computer vision is to realize the task to make computer refers to the human visual function, hoping to make a meaningful judgment on realistic goals and scenarios based on perceived images (Shapiro, 2001). This is just also the goal of understanding.

An important task in computer vision and image understanding is to analyze the scene through image operation on the image of scene in order to guide the action. To do this, one needs to locate the objects in the scene, and to determine how they change its position, attitude, speed and relationships in the space over time. In short, it is to grasp the action in time and space, to determine the purpose of the operation, and thus to understand the semantics of the information they passed. This is refereed as the understanding of spatial-temporal behaviors.

Behavior-based automatic target image/video understanding is a very challenging research issue. It includes the access of objective information (image/video acquisition sequence), the process

of relevant visual information, the analysis of contents (expression and description), as well as the interpretation on the basis of the image/video information, in order to achieve learning and recognition of behavior.

BACKGROUND

Research forces and results around such a topic are just appeared in recent years, some statistics can be seen from the survey on image engineering (Zhang, 2015c). The annual survey series of the yearly bibliographies on image engineering has started in 1995 and has been carried out for 21 years (Zhang, 2016). When the series enters its second decade (for the literature statistics of 2005), with the appearance of some new hot spots in the image engineering research and application, a new subcategories (C5): spatial-temporal technology (including 3-D motion analysis, gesture and posture detection, object tracking, behavior judgment and understanding) has been added into the image understanding category (C) (Zhang, 2006). The emphasis here is the comprehensive utilization of a variety of information possessed by the image/video in order to make the according interpretation for the dynamics of scene and objects inside.

In the past eleven years, the number of publications belong to the subcategory C5 in the annual survey series has attend a total of 153. There are five subcategories in category C, and the total number of publications belong to category C in these eleven years is 1352, so the subcategory C5

Figure 1. Some statistics of the numbers of publications for spatial-temporal technology

is still a small subcategory. Their distributions in each years are shown in the bars in Figure 1, in which a 3-order polynomial curve fitting to the number of publications of each year is drawn to show the change trends. Overall, this is still a relatively new field of research, so its development is not too stable, yet.

MAIN FOCUS OF THE ARTICLE

The definition, development, and stratification of spatial-temporal technology are first provided. Then, from low-level to high-level, the detection of points of interest, the forming of dynamic trajectory and activity path, the example techniques for action classification and recognition, as well as modeling for action and activity, are introduced consecutively. Several further research directions are discussed before some final concluding remarks are delivered.

Spatial-Temporal Technology

Spatial-temporal technology is oriented to the understanding of spatial and temporal behavior. Currently, the main target of the research on spatial-temporal technology is a moving person or object, and the object (particularly a human) changes. According to the expression level of abstraction and description, it can be divided into multiple levels from bottom to top.

1. **Action Primitives:** Atomic units to build a significant action, generally corresponds to a short period of motion information in the scene.
2. **Action:** A series of acts composed of a number of action primitives, a collection of ordered and meaningful models, generally represents a simple execution often carried out by one person, and often lasts only seconds in duration. The results of human actions often lead to changes in body posture and/or object position.
3. **Activity:** A series of actions performed by the host/initiator (mainly emphasize logic combinations). It is a relatively large-scale sports events, generally depends on the environment and people in interaction (Aggarwal, 2011). It is often an occurrence or a consequence of complex operations performed by more than one person, and often last for a relative long period of time.
4. **Event:** It refers to certain activities occurred in specific periods and specific spatial location. Typically one of the actions performed by a plurality of host / initiator (group activity). Detection of specific events often associated with abnormal activities, an overview on this can be seen from (Popoola, 2012).
5. **Behavior:** Subject/initiator mainly refers to a human or animal, emphasizing the body/originator dominated by ideological change action in a particular environment/context, the ongoing activities and describe events.

The following five table tennis pictures, for instance, provide some typical examples (Figure 2). Player's leg lifting, racket waving, etc. can be seen as typical action primitives in table tennis. Players complete a ball serving (including ball tossing, arm swing, wrist shaking, ball hitting, etc.) or a ball returning (including the pace moving, arm outstretching, wrist flipping, ball stroking, etc.) are typical types of action, but one player went to apron and pick a ball are often seen as an activity. The two players hit the ball back and forth in order to win points is a typical scene of activity. Competition between teams is generally viewed as an event, so as a wonderful shot, and the awarding after the match is also a typical event. Fist after winning of players can be seen as a self-motivated action, but more often it is seen as a behavior of the players. When players made good exchange, the applause of the audience, as well as shouting, cheering, etc., are also attributed to the behavior of the audience.

It should be noted that the concepts of the last three levels are often not strictly distinguished in many practical studies. For example, some activities are called events, this generally refers to some unusual activities (such as the disputes between two persons, the falling of an elderly person, etc.). Sometimes, the activities are referred to as behavior, it emphasis more on the meaning of activities and the particularity of activities (such as burglary behaviors or over the wall burglary theft). On the other side, they are often closely related. For instance, many human activities are directly related to their behavior (Khair, 2012). In the following discussion, unless special emphasis

would be made, the (generalized) activity will be used as the main representatives of three levels.

The research in spatial-temporal technology has been conducted from points (point of interest) to curves (trajectory of object = multiple points), to surfaces (allocation of activity = compound curves), and to volume (variation of behaviors = stack of surfaces).

Spatial-Temporal Points of Interest

Scene changes come from the motion of objects in the scene, especially accelerated motion. In video of scenes, the accelerated motion of partial structures corresponds accelerated motion of objects, they are at some particular positions in the image, with unconventional change values. The information on these positions (called points of interest) are helpful for understanding the scene.

First consider still images. The modeling of image $f(x, y)$ can be made with the help of linear scale space L , $L: \mathbf{R}^2 \rightarrow \mathbf{R}$:

$$L(x, y; \sigma_l^2) = g(x, y; \sigma_l^2) \otimes f(x, y) \quad (1)$$

where g is a Gaussian kernel with variance σ_l^2 :

$$g(x, y; \sigma_l^2) = \frac{1}{2\pi\sigma_l^2} \exp\left[-\frac{(x^2 + y^2)}{2\sigma_l^2}\right] \quad (2)$$

The idea behind the typical Harris detector of interesting points is to determine the spatial locations in $f(x, y)$ with significant change in both horizontal and vertical directions. For a

Figure 2. Some typical frames of images from a table tennis game

given observation scale σ_l^2 , these points can be computed with the help of the matrix of second order moment that is obtained by summation in a Gaussian window with variance σ_l^2 :

$$\begin{aligned} \mu(x, y; \sigma_i^2, \sigma_l^2) &= g(x, y; \sigma_i^2, \sigma_l^2) \otimes \\ &\left\{ \left[\nabla L(x, y; \sigma_l^2) \right] \left[\nabla L(x, y; \sigma_l^2) \right]^T \right\} \\ &= g(x, y; \sigma_i^2, \sigma_l^2) \otimes \begin{bmatrix} (L_x)^2 & L_x L_y \\ L_x L_y & (L_y)^2 \end{bmatrix} \end{aligned} \quad (3)$$

where L_x and L_y are the Gaussian differentials at local scale σ_l^2 . The eigenvalues λ_1 and λ_2 form a change descriptor of $f(x, y)$ along two directions, respectively. If both λ_1 and λ_2 have large values, then a point of interest exists. To detect such points, the positive maximum of corner point function can be computed:

$$H = \det(\mu) - k \text{trace}^2(\mu) = \lambda_1 \lambda_2 - k(\lambda_1 + \lambda_2)^2 \quad (4)$$

The above computation for points of interest in spatial space can be extended to spatial-temporal space for detection of spatial points of interest in a particular location on time. This tendency is started around 10 years ago (Laptev, 2005). Detection of such points is essential for extracting low level motion features, and no background modeling is required.

For modeling spatial-temporal image sequence, start from $L, L: \mathbf{R}^2 \rightarrow \mathbf{R}$, and convolve it with non-isotropic (space variance σ_l^2 and time variance τ_l^2 are not correlated) Gaussian kernel to form a linear scale space $L, L: \mathbf{R}^2 \times \mathbf{R} \rightarrow \mathbf{R}$.

$$L(x, y; \sigma_l^2, \tau_l^2) = g(x, y; \sigma_l^2, \tau_l^2) \otimes f(x, y) \quad (5)$$

where the Gaussian kernel for the separation of space and time is

$$g(x, y, t; \sigma_l^2, \tau_l^2) = \frac{1}{\sqrt{(2\pi)^3 \sigma_l^4 \tau_l^2}} \exp \left[-\frac{x^2 + y^2}{\sigma_l^2} - \frac{t^2}{2\tau_l^2} \right] \quad (6)$$

Similar to the spatial domain, a spatial-temporal matrix of second order moment is a 3×3 matrix containing spatial differentials of space and time that convolved with Gaussian function $g(x, y; \sigma_l^2, \tau_l^2)$:

$$\mu = g(x, y; \sigma_i^2, \tau_i^2) \otimes \begin{bmatrix} L_x^2 & L_x L_y & L_x L_t \\ L_x L_y & L_y^2 & L_y L_t \\ L_x L_t & L_y L_t & L_t^2 \end{bmatrix} \quad (7)$$

where the first order differentials are

$$\begin{aligned} L_x(x, y; \sigma_l^2, \sigma_l^2) &= \partial_x (g \otimes f) \\ L_y(x, y; \sigma_l^2, \sigma_l^2) &= \partial_y (g \otimes f) \\ L_t(x, y; \sigma_l^2, \sigma_l^2) &= \partial_t (g \otimes f) \end{aligned} \quad (8)$$

To detect a point of interest, the search for μ with significant eigenvalues λ_1 , λ_2 , and λ_3 is conducted. This can be accomplished by extending eq.(4) to spatial-temporal domain:

$$H = \det(\mu) - k \text{trace}^3(\mu) = \lambda_1 \lambda_2 \lambda_3 - k(\lambda_1 + \lambda_2 + \lambda_3)^3 \quad (9)$$

Dynamic Trajectory Learning and Analysis

Dynamic trajectory learning and analysis attempt to provide certainty for monitoring the state of the scene by understanding and characterization of the change of each target position and the moving results (Morris, 2008). A flowchart for dynamic trajectory learning and analysis in video is shown in Figure 3. First, the target is detected and tracked; then, the scene model is automatically constructed with the trajectory obtained; finally, the model is used to monitor the situation and provide labels for the activities.

In the scene modeling, the points of interest (POI) are first determined within an image area and considered as the location where some events happening, then in the learning step the activities

Figure 3. Flowchart for dynamic trajectory learning and analysis

are defined along an activity path (AP). The path is to characterize how the target moving between the points of interest. Such constructed models can be called POI/AP model.

The main tasks in the POI/AP Learning include:

1. Activity learning;
2. Adaption;
3. Feature selection.

Automatic Scene Modeling

Modeling scenarios by means of dynamic trajectory automatically include the following three tasks (Makris, 2005):

1. **Object Tracking:** It needs for each observable object to achieve identity maintenance in each frame. For example, pedestrians can be detected by camera installed on a moving car (Jia, 2007).
2. **Points of Interest Detecting:** The first task in image scene modeling is to figure out a region of interest. In topographic map for object tracking, these regions correspond to the nodes in the graph. Two types of nodes mostly considered are in/out regions and stop regions.

In/out regions are the locations of the objects to enter or leave the field or the locations of tracked objects appear or disappear. Stop regions come from scene landmark points, that is, the positions that an object tends to stay over a period. There are two different ways for locating stop regions. One is to find the region inside which the tracked points have moving speed lower than a pre-determined threshold; another is to find the region inside

which the tracked points keep in a limited distance range within a certain period.

3. **Active Path Finding:** To understand the behavior, the active path (AP) needs to be determined. This can be obtained by filtering out false alarms or tracking interrupted noise from training set with POI, keeping only the paths started after entering the region and ended before leaving the region. An activity of interest should be defined between the two end points (points of interest).

Active Path Learning

As the active path provides the information for object motion, an original trajectory can be represented by a sequence of dynamic measurements. For example, a common representation for trajectory is often a motion sequence:

$$Diam(B) = \max_{i,j} [D(b_i, b_j)] \quad b_i \in B, \quad b_j \in B \quad (10)$$

where the motion vector is

$$Diam(B) = \max_{i,j} [D(b_i, b_j)] \quad b_i \in B, \quad b_j \in B \quad (11)$$

It represents the dynamic parameters obtained from the object tracking at time t , i.e., position $[x, y]^T$, speed $[v_x, v_y]^T$, and acceleration $[a_x, a_y]^T$.

It is possible to learn AP, with unsupervised way, by using only the trajectory. The basic process is shown in Figure 4 that includes three steps.

1. **Pre-Processing:** It consists of two tasks, normalization to ensure that all the paths have

Figure 4. Steps for path learning

the same length; dimension reduction for mapping the paths to a new low-dimensional space to perform more robust clustering.

2. **Clustering:** In order to produce meaningful clustering, three considerations are the definition of a distance measure (corresponding to similarity), the updating policy for clusters, and the clustering validation.
3. **Modeling:** Two methods can be used, as shown in Figure 5. One considers the complete path by using the cluster centers and the envelopes (to indicate the range of path), as in Figure 5(a). Other one divides the whole path into a number of sub-paths (using tree structure), as in Figure 5(b).

Automatic Activity Analysis

Once the scene model is established, then the activities and behaviors of the objects can be analyzed. In addition to simply identify a particular behavior, all atypical events need to check. By observing a scene for long time period, the system can analyze a series of activities, and can further learn to find what the event of interest is.

Some typical activity analysis examples are:

1. **Virtual Fencing:** Any monitoring system has a monitoring range. By setting up early warning on the border, an equivalent virtual

fence is established, and the invasion will trigger system to start an analysis procedure.

2. **Speed Profiling:** Virtual fencing uses only position information, while tracking can also provide dynamic information for speed-based early warning.
3. **Path Classification:** Speed profiling uses only the current tracking data, while activity path (AP) can also provide historical information to predict and interpret the coming data.
4. **Abnormality Detection:** Since the activity path can indicate the characteristics of typical/normal activities, if the new path shows certain differences, an abnormality will be detected.
5. **Online Activity Analysis:** Enabling online analysis, identification, and evaluation of activities would be more powerful and useful than just describing the activity with the path. An online system needs to inference the current behavior based on incomplete data.
6. **Object Interactive Characterization:** Even higher level analysis is expected to explain the interaction among different objects, their motions may need a group of paths, and their activities may need several image sequences.

Figure 5. Two methods for path modeling

Action Classification and Recognition

Vision-based human action recognition is a process to use action labels for marking an image sequence (video). On the basis of obtaining the representation of the observed image sequence or video, this process can be turned into a classification problem.

Action Classification

Many techniques for action classification have been proposed (Poppe, 2010).

1. **Direct Classification:** It does not pay special attention to the time domain, even the video is used. The related methods put all observed information (from all frames) into a single expression, or identify and classify actions separately for each frame. As high-dimensional representation for image is required, a large number of computation is inevitable.
2. **Time Status Model:** Both generative models and descriptive models can be used. Generative models learn the joint distribution between observation and action, and model each action class. Typical generative models include hidden Markov model (HMM), maximum entropy Markov model (MEMM), etc. Descriptive models learn the conditional probability to observe the action class. They do not concern for the class model, but for the difference between classes. Conditional random fields (CRF) is an often used descriptive model.
3. **Action Detection:** It does not explicitly model the object representation in the image, nor the action in the image. It connects the observed sequence with the labeled video sequence to directly detect (defined) actions. The main methods for action representation and description can be classified into two groups: appearance-based and body model-based.

Action Recognition

Many methods for action recognition have been developed. They are depended on the purpose of the research and the application domain (Moeslund, 2006). For monitoring systems, the human activity and human interaction are considered. For scene interpretation, representation can be independent from the objects inducing the motion.

1. **Holistic Recognition:** It puts the overall emphasis on the whole body identification or on identifying each individual part of single person. Most techniques are based on human silhouette or outline, and they have less distinction among various parts of the body.
2. **Posture Modeling:** Recognition of human action is closely related to the body posture estimation. Body posture can be divided into action attitude and postural attitude (gesture). The former corresponds to the movement behavior at a certain moment, while the latter corresponds to the orientation of human body in 3-D space. The main methods for posture representation and description can be classified into three groups: appearance-based, body model-based, and 3-D reconstruction-based.
3. **Activity Reconstruction:** Action results in a change of posture. If each stationary body posture is defined as a state, then the building of a sequence of actions (activity) can be obtained by conducting a traversal through the corresponding attitudes of the state, with the help of state-space method (also known as probability Cyber Law). Based on such a sequence of actions (activity), body action and posture can be recovered.
4. **Inter-Activity:** Inter-activity is relative complex. Two main types can be distinguished: interaction between human and environment; interaction among different persons. In the former, the human is the initiator of the activity, such as taking a book up from

a table, driving a car on the road, etc. This can be referred as single (person) activity. In the latter, the human interacts each other. It often refers to the exchange activities or contact behavior of two (or multiple) persons. It can be seen as the combination of several single (atomic) activities.

5. **Group Activity:** Many quantitative changes may cause a qualitative change. Large number of objects involved in the activity could pose new problems and require new solutions. Semantic analysis of the polymerization, dissipation, differentiation, and combination of object groups becomes indispensable for capturing the tendency and situation of whole scene.
6. **Scene Interpretation:** Different from recognition of objects in scene, scene interpretation considers to comprehend the entire image rather than to verify a particular person or object. In practice, many methods do recognize activity by only observing the motion of objects in the images, without determining the identity of objects.

Modeling Activity and Behavior

A general action/activity recognition system should perform, from an image sequence to high-level interpretation, several tasks (Turaga, 2008):

1. Capturing input video or image sequence.
2. Extracting low-level image features.
3. Describing middle-level actions.
4. Interpreting image with high-level semantics.

General practical activity recognition system has hierarchical structure. In the low-level, there

are modules for foreground-background separation, for object detection and tracking. In the middle level, the main module is for action recognition. In the high-level, the most important module is inference engine, which understands activity with the aid of learning.

From an abstract point of view, the level of activity is higher than that of action. From the technology point of view, modeling and recognizing the action and activity often using different techniques. A categorization scheme is shown in Figure 6 (Turaga, 2008).

Action Recognition

The methods for action recognition can be divided into three groups: non-parameter modeling, volume modeling, (timing) parameter modeling.

1. **Non-Parameter Modeling:** It extracts, from each frame of video, a group of features, and matches these features with stored templates. Typical methods include: using 2-D template, using 3-D object model, manifold learning, etc.
2. **Volume Modeling:** It does not extracts features from each frame of video, while considers video as a collection of 3-D voxels, and extend the standard 2-D image features (such as scale space extreme values) to 3-D. Typical methods include: spatial-temporal filtering, using parts of 3-D space (for example, spatial-temporal points of interest), sub-volume matching, tensor-based methods, etc.
3. **Parameter Modeling:** It dynamically models the motion time, and estimates the specific parameters for a group of actions

Figure 6. Classification of approaches for action and activity recognition

from training sets. It is more suitable for complex actions cross over different time domain. Typical methods include: hidden Markov model (HMM), linear dynamic system, non-linear dynamic system, etc.

Activity Modeling and Recognition

Compared to action, activity not only has long duration but also often involve many initiators. For modeling complex scenario, it is necessary to perform high-level representation and reasoning for the intrinsic structure and semantics of behavior (Zheng, 2012). The methods for activity modeling and recognition can be divided into three groups: by means of graphic model, with the help of syntax, using knowledge.

1. **Graphic Model:** Belief network (such as Bayesian network) and Petri net are two popular networks used, which can be represented by graph.
2. **Syntax Methods:** Two key points for syntax methods are grammar and rule. The grammar uses a group of generative rules to describe the structure under considerations, so as to model body motion and multiple-person interaction. Stochastic context-free grammar has been used for modeling semantic of activity.
3. **Knowledge Methods:** Knowledge is closely related to logic. Logic rules are suitable for representing input knowledge and high-level reasoning results, so they can be used to describe general domain knowledge for activity explanation. Ontology can standardize the definition of activity, increase inter-operability among different systems, and compare the performance of various behavior assessments.

FURTHER RESEARCH DIRECTIONS

Spatial-temporal behavior understanding is a relatively new field of research, many future research works are required, and several potential directions are:

1. As can be seen from the above introduction and discussion, research in this field has gone from points to curves, from curves to surfaces, and from surfaces to volumes. What would be the next step?
2. Action and activity, both are the physic bases of behavior. They are often the most significant and also the most attractive parts of image and video. In this regard, the attention-based recognition techniques (Zheng 2015) should be beneficial.
3. With big data collected from all areas, from one side, a large number of situations requiring behavior understanding arise; from other side, using data mining techniques, it is possible to learn some effective information for accomplish such tasks. To this end, content based visual information retrieval would be called for behavior classification (Zhang 2015b).
4. Deep learning, more general, machine learning, technology has been proved being a powerful tool in many information processing task recently (Zhang 2015a; Zheng 2014; Zheng 2016). How to efficiently use this new technology for understanding of spatial-temporal behavior is expected.

CONCLUDING REMARKS

This chapter introduces a cutting-edge research field of computer vision and image understanding – the spatial-temporal behavior understanding. The main concepts, the focus of research, the typical technology, the fast development, etc. of this new field in recent years are overviewed. From the research advances and trends in the five

levels of spatial-temporal technology, the most of current research efforts seems going to the more challenging high levels. From the point of view in considering the scope of the study involved in the content, except for image technology itself, medicine, psychology, behavioral science, cognitive science, sociology and other disciplines will also play an active role in the future.

KEY TERMS AND DEFINITIONS

Clustering: Clustering is also called unsupervised learning and is a powerful technique for pattern classification. It is a process to group, based on some defined criteria, two or more terms together to form a large collection. In the context of image segmentation, it is often considered as the multi-dimensional extension of the thresholding technique.

Computer Vision (CV): A field that includes methods for acquiring, processing, analyzing, and understanding images from the real world in order to produce numerical or symbolic information, e.g., in the forms of decisions. A theme in the development of this field has been to duplicate the abilities of human vision by electronically perceiving and understanding an image. Computer vision has also been described as the enterprise of automating and integrating a wide range of processes and representations for vision perception.

Deep Learning (DL): A new area of machine learning research. It uses a cascade of many layers of nonlinear processing units for feature extrac-

tion and transformation. Each successive layer uses the output from the previous layer as input. It also learns multiple levels of representations that correspond to different levels of abstraction. Deep learning algorithms are based on distributed representations. The composition of a layer of nonlinear processing units used in a deep learning algorithm depends on the problem to be solved.

Image Classification: Aims at associating different images with some semantic labels to represent the image contents abstractly. To achieve this goal, various machine learning and pattern recognition techniques could be used.

Image Engineering (IE): An integrated discipline/subject comprising the study of all the different branches of image and video techniques. As a general term for all image techniques, it could be considered as a broad subject encompassing mathematics, physics, biology, physiology, psychology, electrical engineering, computer science, automation, etc. Its advances are also closely related to the development of telecommunications, biomedical engineering, remote sensing, document processing, industrial applications, etc.

Image Techniques: A collection of various branches of techniques for processing (such as acquiring, capturing, sensing, storing, enhancing, filtering, de-blurring, in-painting, transforming, coding, transmitting, manipulating, etc.) analyzing (such as segmenting, representing, describing, featuring, measuring, classifying, recognizing), and understanding (such as modeling, registering, matching, reconstructing, training, learning, reasoning, interpreting, etc.) images.

Image Understanding (IU): One of three layers of image engineering, which transforms data extracted from images into certain commonly understood descriptions, and makes subsequent decisions and actions according to the interpretation of the images.

Machine Learning (ML): A powerful tool for pattern classification. It uses the theory of statistics in building mathematical models, and programs computers to optimize a performance criterion using example data or past experience.

Forensic Investigations in Cloud Computing

Diane Barrett

Bloomsburg University of Pennsylvania, USA

INTRODUCTION

Cloud computing environments add an inherent layer of complication to a digital forensic investigation. The content of this article explores current forensic acquisition processes, why current processes need to be modified for cloud investigations, and how new methods can help in an investigation. A section will be included that provides recommendations for more accurate evidence acquisition in investigations. A final section will include recommendations for additional areas of research in the area of investigating cloud computing environments and acquiring cloud computing based evidence.

BACKGROUND

Cloud Computing Environments

Cloud computing is encompassed in the capabilities of almost all existing technologies. The concept behind cloud computing is a production environment in which resources and software services do not function locally. Instead, the Internet or the internal network of an organization seamlessly connects numerous host machines running on a virtualized platform (Budriene & Zalieckaite, 2012).

Pallis (2010) provides a general layered architecture of cloud infrastructures as a basic model by classifying the architecture into three abstract layers using two models: deployment and service, along with a set of characteristics. The layers

from the bottom up are infrastructure, platform, and application. The infrastructure layer provides fundamental computing resources such as processing, storage, and networks. The platform layer delivers higher-level services and abstractions for integration of the ability to perform application functions in the environment. The application layer allows the capability for applications as a service (AaaS).

These three layers are further broken down into service models, deployment models, and attributes. The three well-recognized cloud service models are infrastructure as a service (IaaS), platform as a service (PaaS), and software as a service (SaaS). The four cloud deployment models are community, hybrid, public, and private. The attributes consist of measured and on-demand self-service, resource pooling, rapid elasticity, and broad network access. This is the exact layered architecture outlined by National Institute of Standards and Technology (NIST) in the final issuance of the cloud computing definition dated September 2011.

Environmental Variables

Complex and dynamic business environments such as cloud computing environments drive organizations of all sizes to respond rapidly to market changes and pursue creative resource saving solutions. In addition to being a technology solution, cloud computing is a new business model. Cloud computing environments offer unrestricted scalability and lower data-center setup costs by using multitenancy.

The multitenancy and virtualization characteristics of a cloud computing environment present difficult implementation demands in the areas of security and access control (Almutairi, Sarfraz, Basalamah, Aref, & Ghafoor, 2012). The unique security and access control challenges presented by the use of multitenancy and virtualization in cloud computing environments exist because many individual environments share the same set of hardware. The sharing of storage blocks can result in the accidental and unauthorized flow of information (Werner, 2011). The diversity of services offered in cloud computing environments requires variable levels of granularity when implementing access control mechanisms. The risk of resource exploitation by unauthorized users is significantly increased when there are insufficient or untrustworthy authorization mechanisms implemented in a cloud computing environment (Werner, 2011).

Cloud computing environments offer many organizational benefits by providing scalable but complex computing infrastructures. Every cloud deployment and service model instance is different. For example, one SaaS implementation can be completely different from the next. There are many newly emerging challenges associated with the use of cloud computing environments and existing issues are not yet addressed. Automated service provisioning, virtual machine migration, server consolidation, and the management of power and security are just beginning to garner research community attention.

Digital Evidence Seizure

Digital forensics focuses on the retrieval and analysis of data found on digital devices relative to some type of unauthorized or criminal activity (Garfinkel, 2010). Traditional digital forensics processes consist of crime scene evidence collection, evidence preservation, evidence analysis, and presentation of the analysis results (Greengard, 2012). Current traditional digital acquisition processes include maintaining chain of custody control of forensic evidence data. This chain of

custody control occurs in the evidence collection phase through the imaging of a system (Decker, Kruse, Long, & Kelley, 2011).

Cloud computing technology disrupts the initial step of evidence collection in conducting a digital forensic investigation. Traditionally, the seizure of forensic evidence occurs through a search warrant or other legal request. In a cloud computing environment, the emphasis is on the cloud provider contract as opposed to a search warrant or legal request because the data can be geographically disbursed and is under the control of the service provider (Dykstra & Sherman, 2011). Cloud contracts play a very important part in forensic practitioner's ability to conduct a sound forensic investigation (Svetcov, 2011). In some cases, the forensic investigator never gets to acquire the evidence. The designated employee at the service provider performs the evidence acquisition and supplies the results to the client, who then sends the information to the investigator (James, Shosha, & Gladyshev, 2013). This is contrary to current forensic practice where legal documents provide the case investigator the ability to acquire the evidence.

In a cloud computing environment, data are spread out amongst numerous servers and other components. When a crime happens, the location of recoverable data includes the client machine, the equipment of the Internet Service Provider (ISP), and the data backups of the cloud service provider (Shin, 2013). This makes acquiring evidence from a crime committed in a cloud computing environment much more difficult since the environment is not localized like it is in a traditional digital forensic evidence acquisition (Dykstra & Sherman, 2011). Traditional imaging cannot be performed because it is not possible to take down and create a forensic image of such a large environment (James et al., 2013).

The digital forensics discipline faces new challenges where cloud computing is concerned (Berman, Kesterson-Townes, Marshall, & Srivathsa, 2012). Traditional forensic evidence acquisition processes do not fit well into cloud

computing because of the way cloud computing works (Svetcov, 2011). Traditional digital forensic acquisition processes focus on individual computers and isolated environments, while cloud computing forensic acquisition processes include the intricacies of complex infrastructures including virtual servers, applications, and diverse operating platforms that may be located in foreign countries (James et al., 2013).

Common forensic procedure is to shut down the system in order to take a forensic image of the system. This procedure cannot apply to hosted cloud services due to disruption of service to a wide scope of users (Cho, Chin, & Chung, 2012). Cloud computing systems consist of multiple user environments, using a variety of services. Shutting down a cloud computing system disrupts services to all the user environments hosted on the system.

When the user or service provider shuts down the virtual machine because of inactivity, service providers reallocate the storage space originally allocated to the virtual machine to other virtual machines (Huth & Cebula, 2011). Upon deletion of the virtual machine and the overwriting of storage space, the evidence disappears (Svetcov, 2011). Although it is possible to recover forensic data from a running virtual machine, if the files associated with the virtual machine are not collected, valuable evidence is missed (Fiterman & Durick, 2010). Associated virtual machine files contain information such as configurations settings and memory content are often not collected as part of the acquisition process.

Two well-known and commonly used commercial cloud services are Amazon Elastic Compute Cloud (EC2) and Rackspace's cloud services. Hosting cloud services on geographically diverse servers using distributed file systems provides scalability and reliability (Cho et al., 2012). Current forensic methods do not exist for analyzing this type of cloud computing environment. The only way to recover evidence is through vendor provided tools that are designed for gathering metrics. Forensic analysis of distributed file systems is very difficult (Cho et al., 2012). Multi-national

web-based organizations such as Facebook and Yahoo use the Hadoop file system. Hadoop is a common distributed file system used in large data environments such as cloud computing. Due to the way the Hadoop file system works, it processes petabytes of data and erasure of forensic evidence could easily go without notice (Cho et al., 2012). The development of Hadoop occurred with fast processing of data in mind and there was very little consideration given to security or forensic analysis capabilities.

Current Cloud Acquisition Approaches

Without a clear understanding of how cloud computing works and the underlying infrastructure components, law enforcement agencies cannot properly investigate cloud computing environments (James et al., 2013). Some forensic practitioners have taken the view that the acquisition of evidence from the cloud is merely an extension of existing actions used to acquire data from a network because the cloud data is stored similar to network data (Adams, 2013). Contrary to this view, there are differences between cloud computing forensics and network forensics. The primary similarities and differences between cloud computing forensics and network forensics stem from the key areas of physical access, logical access, segregation of evidence, methodology, and legal considerations.

Ruan, Carthy, and Kechadi (2012) proposed that cloud forensics is a subsection of network forensics and a cross-discipline between cloud computing and digital forensics, adopting the same definitions of cloud computing and digital forensics provided by NIST. The methodology used originates at three distinct dimensions: legal, technical, and organizational. Choosing this methodology encompasses jurisdictional issues, the lack of international cooperation, and formation of foundational standards and sound policies. Ruan et al. (2012) developed a high-level conceptual model that analyzed the forensic im-

part of cloud computing environments based on deployment models, service offerings, cloud actor roles, segregation of duties, and forensic artifacts obtainable from the environment.

Adams (2013) proposed the advanced data acquisition model (ADAM). The model breaks down forensic processes into three main functions derived from analysis of previous models introduced between the years 2001 and 2004. The actions in the first stage occur upon notification of the scope of work to the investigator. The activities in this stage happen prior to arriving at the incident location. In the next stage, the investigator prepares for the data acquisition upon entry of the incident scene. The final stage consists of acquiring and handling the evidentiary data.

Adams (2013) used a distinctions, systems, relationships, and perspectives (DSRP) thinking patterns in creating ADAM, tying scientific thinking to the forensic processes. Initial testing of ADAM compared ADAM to the processes used in three previous investigations. The results produced a viable model because cases in Australia and New Zealand are seeing flowcharts introduced as a manner in which to help the jury and court understand scientific forensic evidence.

Shende (2010) approached the digital investigations of cloud computing environments as the mapping of computational and storage structures falling within the investigative scope. Emphasizing the cross boundaries of responsibility and access, service level agreements play a large part in the ability to investigate a cloud computing environment. The key to data access in cloud computing investigations lies in the dialogue between the organization and cloud service vendor in establishing incident response requirements, processes, and protocols when drafting a service level agreement (SLA) (Shende, 2010).

Lu, Lin, Liang, and Shen (2010) proposed using a secure source structure based on the bilinear pairing technique to deliver reliable digital forensic evidence in cloud computing environments. Using a cloud computing architecture comprised of a cloud service provider (SP), a trusted sys-

tem manager (SM), and an enterprise size user environment, the secure provenance SP method demonstrates confidentiality of information, authorized access, anonymous authentication, and ownership tracking. Extending this method for forensic use provides ownership information associated with every version of a document to the SM. The SM then uses an ownership-tracking algorithm to follow the evidence to a unique user identity. This proposed design encompasses a wide range of security features, making it ideal for use in the forensic investigation of cloud computing environments.

Witek and Daranyi (2012) took an approach similar to Lu et al. (2010), in that the work focused on the tracking of digital assets. Using a digital preservation (DP) policy methodology ensures that digital objects remain valid over an extended time period. Cloud computing infrastructure provides a platform ad-hoc computation along with distributed digital preservation. Witek and Daranyi (2012) proposed a middleware solution in the business services layer of the Sustaining Heritage Access through Multivalent Archiving (SHAMAN) core infrastructure. The business layer serves as the intermediary between the top presentation layer and the lower infrastructure layer. The proposed solution has promising future implications for digital preservation.

Current Theory Approaches

Bayesian theory and Dempster-Shafer theory are among the few theories that have any documented research on forensic application. There is widespread use of Dempster-Shafer theory in information security because it applies in many areas such as risk assessment, attack analysis, and forensic image analysis. In forensic analysis, combining Dempster-Shafer theory with other theories and methodologies allows a more accurate means to identify evidence. Current methods of application using Bayesian theory and Dempster-Shafer theory have limitations where cloud computing is concerned (Zhou & Mao, 2012). Bayesian and

Dempster-Shafer approaches use the mathematics of probability theory and numerical measures of uncertainty. These theories are applicable in intrusion detection systems, data mining techniques, and data privacy, but cloud computing environments have too many variables to postulate correct hypotheses for successful mathematical calculation (Chou, 2011). Additionally, the objective of the research is to provide a framework for human use. Bayesian and Dempster-Shafer theories are machine-based applicable theories that are not conducive to human application (Zhou & Mao, 2012).

Although there is proven application of Dempster-Shafer to forensic image analysis, this is a limited use application. Little is known about the application of current forensic evidence acquisition methods to cloud computing environments (Lallie & Pimlot, 2012).

APPLYING TRADITIONAL ACQUISITION METHODS TO CLOUD COMPUTING

Although there are theories about when traditional forensic acquisition methods are applicable in cloud forensic environments, when the methods can be modified, and when new methods are required, it is not currently known which traditional forensics methods apply to cloud computing environments, which traditional processes can be modified, and when new methods are required to be developed. Carlton (2007) used a grounded theory methodology to identify the tasks forensic examiners perform during forensic data acquisitions. Carlton's (2007) study identified distinct acquisition procedures for live or running systems that include performing a random access memory (RAM) dump, collecting volatile data, performing a live acquisition, and determining the programs currently running. Concluding tasks commonly used by examiners include preserving and sealing original acquisition media, placing original media in an evidence vault, performing an inspection to

verify the acquired image is readable, and creating a restore image of the original media for return to the owner (Carlton, 2007).

The acquisition tasks of Carlton's (2007) survey were reviewed for relevance and the 20 top ranked tasks were selected. A panel of international experts then reviewed the tasks for applicability to cloud computing environments. The findings indicated that about 50% of the current digital acquisition processes applied to cloud computing environments; the rest required modification or new process development. Post-acquisition processes were most suited for application in cloud computing environments. Following post-acquisition processes in order of applicability were live acquisition processes. The main limitation in this area was access to the cloud server in order to perform the processes. The results analysis suggested this category of processes had solutions for digital evidence acquisitions in cloud computing environments because the processes were modeled after already established network forensic processes.

Ten percent of the 20 pre-selected traditional forensic processes required the development of new processes for the forensic acquisition of digital evidence in cloud computing environments. The panel experts agreed that current acquisition processes in the category of dead drive acquisitions did not fit into cloud computing environments and many of the processes should no longer be included because they were not applicable or modifiable. From the results, the contingency framework shown in Table 1 was built based on the understanding of when current traditional forensic processes apply, identifying when process modification is acceptable, and when the development of new processes is required for forensic evidence acquisitions in cloud computing environments. The categories for forensic evidence acquisition activity are summarized as pre-acquisition, acquisition, imaging, and post-acquisition processes.

The digital forensic acquisition cloud contingency model combines the key contributions from the process design contingency model proposed

Table 1. Contingency framework

Process Category	Recommended Application	Contingency Variable(s)
Pre-acquisition processes	Modification	Fluidity of environment
Live acquisition processes	Application with limitations	Access, tools, scope
Dead acquisition processes	Partial application, modification or develop new	Cloud implementation, access
Imaging processes	Application, modification or develop new	Cloud implementation, access, scope
Post-acquisition processes	Application with limitations	Fluidity of environment, access

by Austin and Devin (2009) and the information security management contingency model demonstrated by Tassabehji (2005).

The model depicts the processes first because processes are the only constant. Once the digital forensic examiner choose the process to be performed, the cloud computing environment uncertainty is introduced which produces the contingency. Based on the contingency, the appropriate application methodology is executed. Figure 1 represents a diagrammatical illustration of the digital evidence forensic acquisition cloud contingency model.

The contingency framework in Table 1 used the panel results as the foundation to create a digital forensic acquisition cloud contingency model, concentrating on how uncertainty and contingencies affect particular processes and guide a course of research that can support and enrich the model. When the world changes in a way that requires different functionality in a process or practice currently used, flexibility allows adjustment of the process or practice to reflect the changed world (Austin & Devin, 2009).

RECOMMENDATIONS

When forensic examiners lack knowledge about the environments from which evidence is being acquired, there is a high likelihood that critical information is missed during the acquisition process (Hale, 2013). Tools will gradually become outdated and computer forensic practitioners will no longer be able to rely on forensic analysis results, unless the forensic community formulates a vibrant strategy for developing methods that build upon each other (Garfinkel, 2010). Cloud forensics is a relatively new area of digital forensic practices with few industry professionals capable of providing required training (Ruan et al., 2012).

Currently, NIST and the Scientific Working Group on Digital Evidence (SWGDE) offer policy and guidance on a federal level. The digital evidence forensic acquisition cloud contingency model does not fit into the SWDGE model because the digital evidence forensic acquisition cloud contingency model has contingent variables requiring deviation from the proven reliable processes established in the SWDGE model (SWDGE,

Figure 1. A diagrammatical illustration of digital evidence forensic acquisition cloud contingency model

2014). When working groups create models on which policy is based, a broader more flexibly model and policy is required to reflect the fluid environment that is now part of every business and most digital forensic acquisitions.

The organizations and universities that build and deliver curriculum in digital forensic areas need to participate in the advancement of the digital forensics field by addressing cloud computing acquisitions. Guidance organizations must work together to provide solid direction in order to establish agreement on basic definitions and simplified models regarding cloud computing environments to help the industry move forward so practitioners accept and implement suggested guidance.

Academia and the digital forensic training community will need to create and encourage the development of new training programs so that practitioners may better respond to situations where the acquisition of cloud computing environments are required. Standards will also have to be set by legal departments where service level agreements are concerned and when other parties must be relied upon to provide evidence. In setting new standards for proper acquisition of forensic evidence in cloud computing environments, organizations must create legal requirement documentation encompassing both vendor contracts and the organization. After the legal requirements are set, digital forensic practitioners have the availability to set best practices, but those best practices will be contingent upon the existing conditions.

FUTURE RESEARCH DIRECTIONS

The opportunity for researchers to make innovative contributions and have a substantial impact on the cloud computing industry has only just begun. The findings in this panel study are a bridge to a very small body of literature, setting the stage for new and promising lines of inquiry. The results of the study produced a contingency framework

and digital evidence forensic acquisition cloud contingency model to help guide a course of research that can test the model.

Using contingency frameworks to address other research questions provides a fresh perspective on the application of digital forensic acquisition methods to cloud computing environments. Additional studies could firmly establish that the choices available for the application of digital forensic methods to cloud computing environments are ingrained in contingency frameworks. One of the significant contributions of this panel study is the identification of contingency factors such as available tools, access, availability, and acquisition scope as the underlying elements when choosing the application of digital forensic methods to cloud computing environments. These contingency factors are easily ported to other evidence acquisition methods for expanding research in this area.

The digital evidence forensic acquisition cloud contingency model suggests other important directions of research. Accepting a contingency perspective on how to choose digital process application in cloud computing environments can serve as a powerful theoretical lens both in interpreting the results of prior models and in shaping rigorous research models for future inquiry. Another direction for future research would be to examine the influence of multiple contingencies on the process application within individual cloud types.

CONCLUSION

As an industry, digital forensics is lacking the tools, published processes, and guidance for proper acquisition of digital evidence in cloud computing environments. Pre-acquisition processes are most suited for modification in cloud computing environments while post-acquisition processes are most suited for application in cloud computing environments. The digital acquisition processes that applied to cloud computing environments were modeled after already established

network forensic processes. The cloud computing environment uncertainty produces contingencies that affect selecting the appropriate acquisition process application.

The result of this panel study was a developed robust contingency framework for deciding when to use traditional forensic acquisition practices, when to use modified processes, and when it is necessary to develop new forensic acquisition processes through the evaluation of 20 conventionally recognized forensic acquisition processes by a panel of experts. The presented contingency framework used the study results as the foundation to create a digital forensic acquisition cloud contingency model, concentrating on how uncertainty of cloud computing environments and contingencies affect particular processes. The contingencies are easily ported to other evidence acquisition methods for expanding research in this area.

KEY TERMS AND DEFINITIONS

Cloud Computing: Cloud computing is an environment in which the Internet or the internal network of an organization seamlessly connects numerous host machines running on a virtualized platform to provide resources and software services.

Digital Forensics: Digital forensics is the division of forensic science that focuses on investigating and analyzing information artifacts located on digital devices involved in computer crime cases.

Infrastructure as a Service (IaaS): IaaS is an Internet delivered virtual environment in which the service provider supplies cloud infrastructure services that can include software, hardware, and networking equipment.

Multitenancy: Multitenancy is a software architecture in which one server hosts a multitude of different virtual environments for unrelated organizations, or tenants.

Platform as a Service (PaaS): PaaS is an Internet delivered virtual environment in which the service provider supplies cloud platform services that include the operating system and other platform-associated services.

Software as a Service (SaaS): SaaS is an Internet delivered virtual environment in which the service provider supplies commercial applications, eliminating associated purchasing and installation costs for the organization.

Service-Level Agreement (SLA): A SLA is a binding contract between service providers and purchasing organizations that specifies the service parameters and recourse if an unexpected business interruption occurs.

Virtual or Virtualized: Virtual or virtualized is a term used to explain the process of running an environment other than the native computing environment. fffffff

Internet–Facilitated Child Sexual Exploitation Crimes

Keith F. Durkin

Ohio Northern University, USA

Ronald L. DeLong

University of Dayton, USA

INTRODUCTION

The computer innovations of the late 20th Century had a transformative impact on society, revolutionizing many aspects of social life including education, commerce, and recreation. These technological developments have also impacted crime. Many types of criminal behavior have changed and new forms emerged in response to the advent of the Internet. Examples include hacking, cyberbullying, fraud, cyberstalking, and gambling. Internet crimes against children are among the most prominent manifestations of this phenomenon.

BACKGROUND

Internet crimes against are defined as those offenses that include an element of computer-facilitated sexual exploitation of minors (Alexy, Burgess, & Baker, 2005). First, the Internet is now the main mechanism for accessing and distributing child pornography. Second is the well-publicized problem of adults soliciting minors for sex. Third, the Internet is used to facilitate the commercial sexual exploitation of children (e.g., sex trafficking of juveniles, commercial distribution of child pornography). Fourth, the Internet serves as a social consolidation mechanism allowing adults with a sexual interest in children to network with each other. Additionally, the Internet plays a secondary role in the victimization of children

by allowing offenders who have a pre-existing relationship with a minor (e.g., family members or acquaintances) to use this medium to facilitate contact offending.

Offenses, Offenders, and Victims

The Internet is now the primary medium for accessing and distributing child pornography. These materials can now be instantaneously shared with, an anonymously accessed, by a global audience. For instance, an Interpol child abuse image data base contains more than a half a million images (Elliot & Beech, 2009). A recent study of the peer-to-peer file sharing network Gnutella found approximately 250,000 American computers shared 120,148 unique child pornography images during a one-year period (Wolak, Liberatore, & Levine, 2014). On the most fundamental level, these images represent a permanent record of the sexual exploitation of a minor (Lanning, 2010). The mere demand for this material fuels the further sexual abuse and exploitation of children (Seto, Hanson, & Babchishin, 2011). Concerns have been raised that this easy access to child pornography online might contribute to a new category of offender who succumbs to temptations that might have otherwise been held in check (Babchishin, Hanson, & VanZuylen, 2015).

Individuals who collect and/or traffic child pornography via the Internet are traditionally referred to as “traders” by law enforcement (Alexy et al., 2005). The National Juvenile Online Victimization

tion (NJOV) studies have gathered data from a national sample of law enforcement agencies regarding arrests for child pornography (Wolak, Finkelhor, & Mitchell, 2011; 2012a; 2012b). The results revealed that offenders in these cases are overwhelmingly single white men over the age of 25. Most of the offenders arrested on child pornography charges had material depicting prepubescent children, and a substantial portion had images of children less than 5 years of age. There appears to be an association between the possession of child pornography and engaging in contact sexual offenses against minors. An examination of 2009 arrest data suggests that one-third of suspects arrested for online child pornography offenses were actively molesting minors (Wolak et al., 2012a). Moreover, a meta-analysis of published studies of online (primarily child pornography) offenders found that approximately 1 in 8 of these men had a prior criminal record for contact sexual offenses (Seto et al., 2011). However, the same analysis found that about one-half of these individuals self-reported committing contact offenses. Similarly, Bourke and Hernandez (2009), who conducted a study of 155 offenders who were serving terms for online child pornography charges, found that although 26% of these men had official criminal records for sex crimes against minors, 85% of these men admitted to having committed at least one contact offense against a minor while in treatment.

A second category of Internet crimes against children involves adults using the Internet to solicit children for sexual purposes. These offenders have been called “travelers” by law enforcement (Alexy et al., 2005), and their online behavior has been referred to a “grooming”, “luring” or “predation” (Urbas, 2010). They engage in sexually orientated communications with minors, often with the intention of arranging offline encounters. They have been the subject of intense media scrutiny in the United States, and police stings aimed at catching these offenders were sensationally featured on the popular television show *Dateline NBC: To Catch a Predator*. Communication is frequently on-going, and a relationship between the of-

fender and target can develop over the course of several weeks or months. These solicitations are sometimes aggressive, and can contain explicit sexual content. Offenders may send pornography to their target, as well as exposing their genitals and masturbating on web cams (Marcum, 2007). They may also encourage minors to send them suggestive or explicit photos (Wolak et al., 2011). The most recent research suggests these offenders are increasingly turning to social networking sites to locate and groom potential victims (Balfe et al., 2015).

It is important to understand that the online behavior of these men frequently constitutes a crime. The sexually explicit communication with a minor may constitute the offense of enticement or importuning (DeLong, Durkin, & Hundersmarck, 2010). However, the media coverage of “Internet predators” tends to give an inaccurate picture of this type of offense. Based on research this evidence, this crime often fits the model of statutory rape, inasmuch as adult men try to develop a relationship with young teens and “seduce” them into an eventual encounter (Wolak, Finkelhor, Mitchell, & Ybarra, 2008). Data from the NJOV studies indicate that over 90% of the victims in these cases are between the ages of 13-17. Most of the victims are female adolescents. Violence or force is used less than 5% of these cases. A study of online solicitation in Europe produced very similar findings (Schulz, Bergen, Schuhmann, Hoyer, & Santtila, 2015). These offenders are normally not pedophiles, rather they are antisocial adult males who are willing to pursue sexual activities with minors who show signs of sexual development but who are below the age of consent (Seto, 2010).

Research has also focused on the risks factors associated with the online sexual solicitation of minors. Results of the second Youth Internet Safety Survey (YISS2), a national study of 11 to 17 year old adolescents, identified various factors that are associated with receiving aggressive online sexual solicitations (Mitchell, Ybarra, & Finkelhor, 2007). These included being female, visiting chat rooms, discussing sexual topics

online, and sharing personal information with individuals they met online. According to Wolak, Evans, Nguyen and Hines (2013), there is a higher risk of victimization for troubled youths, such as those with a history of abuse or poor parental relations, as well as boys who are gay or questioning. Many of the minors who are solicited online are not stereotypical innocents. These young people may be curious and rebellious adolescents who are actively seeking sexual information or contact (Lanning, 2010).

The Internet is playing a major role in the commercial sexual exploitation of juveniles (Mitchell, Jones, Finkelhor, & Wolak, 2011). With these offenses, children are exploited as commodities in the pursuit of profit. One example that is receiving a great deal of public attention is juvenile prostitution. Classified advertisement sites such as Craigslist can be used by the purveyors of child prostitution to place advertisements complete with a physical description of available children to potential consumers online (McCabe, 2008). In a study of Internet-related juvenile prostitution cases, Wells, Mitchell, and Ji (2012) discovered more than two-thirds of the victims were age 15 or younger, and in more than one-quarter of these cases the adult exploiter was a family member or acquaintance of the victim. The Internet is also used to promote sexual tourism. This phenomenon, which involves traveling with the intent to engage in sexual behavior, often, involves child victims. For a number of years, sex tours in Southeast Asia involving juvenile workers have been promoted via the Internet (Hughes, 2000). There have been reports of pedophiles trading information about potential child victims for pedophiles traveling abroad (Holt, Blevins, & Burkert, 2010).

Moreover, the Internet can serve a networking or social consolidation function for individuals who are sexually attracted to children. There is an entire subculture online of adults with a sexual interest in minors (Holt et al., 2010). This consists of a myriad of websites, computer forums, and

chat rooms. Adult-child sex advocacy groups such as NAMBLA (the North American Man/Boy Love Association) are remarkably active online. There is a vast array of literature, such as BoyWiki and The Boylove Manifesto, which supports the pedophile viewpoint (Durkin & Hundersmarck 2008). Although this networking is generally not criminal (Lanning, 2010), there are serious concerns that these networks may encourage criminal conduct. Research on this phenomenon has concluded these sites were criminogenic since they foster relationships among users and expose these users to rationalizations and justifications (e.g., this behavior does not harm children, children can freely consent to sex with an adult) conducive to sexual offending (Balfie et al., 2015; D'Ovidio, Mitnam, El-Burki, & Shumar, 2009; Durkin & Bryant, 1999; O'Halloran & Quayle, 2010). Furthermore, Schulz et al. (2015) found that among adults who solicit juveniles online, those individuals who participate in pedophilia websites and forums are much more likely to target minors age 13 and younger.

The Internet also plays a secondary (rather than primary) role in the sexual abuse of children. An offender can use computer technology to facilitate sex crimes against juveniles whom they already have a face-to-face relationship with (Wolak et al., 2012b). These offenders can be relatives, teachers, people in the ministry, coaches, or family friends. They can use chat or e-mail to seduce or "groom" the victim, as well as to arrange meetings where the abuse will occur. Data from an NJOV study reveals that nearly half of the victims in these cases are between the ages of 6 and 12 (Mitchell, Finkelhor, & Wolak, 2005). This is significant since the supra majority of victims in Internet initiated cases are older juveniles (between the ages of 13 and 17). Additionally, Internet pornography, including child pornography, can be used by sex offenders to lower the inhibitions of children they already have a face-to-face relationship with, thus facilitating their eventual victimization (Lanning, 2010).

Assessment and Classification of Internet Sex Offenders

Since this is a relatively new type of offending many different types of general sex offender assessments are currently utilized (e.g., pre-sentence, treatment planning and placement, classification, and risk assessment). Due to the unknown elements of associated with this type of offender; risk-level appears to be most requested type of assessment. Additional goals of this assessment should focus level of deviance, identification of pro-offending attitudes, accountability, level of denial and general psychosocial areas (see DeLong et al., 2010). Questions should be formulated in a manner to ascertain the degree, nature, and extent of the sexual and legal problems of the offender. Important in this process is the clinician's ability to address areas that may be uncomfortable for general practitioners such as sexual practices, fantasy, use and description of sexually explicit materials (including child pornography)(Quayle & Taylor, 2002). One should be aware of the offender's level of guardedness and defensiveness, as well as their possible high degree of shame and guilt. Asking questions in a gentle, nonjudgmental and non-confrontational manner is imperative to have an environment where the offender can discuss their offense dynamics and private areas of their life without the fear of judgment and retribution.

Quayle and Taylor (2002) developed a four factor framework that could be utilized in a semi-structured setting in order to address Internet specific issues during an assessment and to identify possible offense cycle dynamics. These four areas are: action, reflection, excitement, and arousal. In *action*, information obtained is from questions addressing length of time on the Internet, contact with others, emotional withdraw from significant others, degree of pleasure received from the activities, level of social isolation, images obtained or developed and sent. *Reflection* focuses on the offender's level of preoccupation with re-living past experiences; details of other online persons contacted; breaking promises about

quitting; and difficulties in concentrating or keeping off-line. *Excitement* addresses degree and type of risks in accessing materials and persons; if the materials were obtained while others were present (especially child pornography with children present); if the offender corresponds with others with a sexual interest in children; and attempts to make contact with children. *Arousal* involves the offender's level of masturbation associated with online activities; changes in sexual behaviors since beginning online activities; changes in the receipt of images and text messages particularly with children; material accessed; and if arousal happens with other non-child images.

Assessing the dynamics of the Internet offending process may help to formulate an explanation of online behaviors in order to understand the motive, intent, and goal(s) of the offender. This will assist the clinician in identifying factors pertinent to establishing treatment goals for the offender. Unfortunately, *the Diagnostic and Statistical Manual of Mental Health Disorders, Fifth Edition* does not identify a specific diagnosis or diagnostic criteria for Internet sex offenders. Therefore, the utilization of offense-specific typologies could appear a logical instrument for the understanding and classification of this population. There are a variety of typologies which attempt to identify a specific set of criteria based on the behavior demonstrated by the online behaviors and processes of the offender (see Seto, 2013 for a listing). These can permit a clinician or other evaluator to simplify and organize the complexities of the behaviors in order to understand similarities and differences in these offenses and offenders. However, it is imperative to note that the typology should be a tool for understanding and assimilating the behaviors, not a diagnosis.

Important in the development of the typologies is Cusson's (1993, in Taylor & Quayle, 2006) multi-stage explanation of the criminal process with Internet sex offenders which focuses on the tasks of search, pre-criminal situations, pre-criminal opportunity, and criminal tactics. This process identifies the following stages: 1) the of-

fender searchers for a need to find a pre-criminal situation, 2) once found the pre-criminal stage is introduced with the potential to commit an offense, 3) once the perceived payoff exceed the risk for the offender, the pre-criminal opportunity is established thereby allowing the offender to seek online communications, and 4) criminal tactics are utilized in order for the offender to demonstrate a sequence of events for the act to occur. Although offenses seemingly well thought out, the offender does not take into account that the actions are restrictive due to the physical limitation of the communicative processes and technologies (Taylor & Quayle, 2006). Therefore, an important consideration involved in whether or not an offender will travel to engage a physical meeting with an intended victim, is the method of communication and ease of transmission regarding messages, images and other items of interests for the offender (Elliot & Beech, 2009; DeLong, et al., 2010).

Treatment of Internet Sex Offenders

Andrews and Bonta (2010) promoted the concept and use of risk, need, and responsivity (RNR), with each area identifying a specific principle in which the offender would be treated. The “*risk principle*” addresses the intensity of services for the offenders should be in line with their level of recidivism risk. Thus, this assumes that the lower risk offender would need less restrictive services versus the high risk offender. The “*need principle*” focuses on the dynamic risk factors which are consistent to the criminogenic needs of the offender. This principle attests that dynamic risk factors which can be changed which are consistent with the offender’s recidivism risk. Finally, the “*responsivity principle*” identifies that when treatment is utilized, the information provided should meet the level and skill of the offender for maximum effect. Although many other factors are important (i.e., client-counselor relationship, genuine approach by the counselor, etc.), the impact by the utilization of the RNR ap-

proach has been found to be a much more effective treatment dynamic (Hanson, Bourgen, Helmus, & Hodgson, 2009).

Since the inception of online offending, treatment options have increased but are not absolute in the consistency of treatment. In fact, the need for separating contact and Internet-only offenders has been addressed as imperative since the treatment needs of each group differs. Seto (2013) identified several treatment programs that have increased in use and awareness. For instance, sexual addiction groups and cybersex addiction programs have increased in availability. A cybersex addictions model has been developed by the Internet Behavior Consulting group, which has a combination of their own workbook, relapse prevention, cognitive therapy, and a 12-step program approach (<http://www.internetbehavior.com>). Because of the research suggesting some Internet-only offenders are lower in risk (Seto, 2013), such treatment would not have to be lengthy or intensive but focused on the dynamics of RNR principals. It would be of importance to assess online behaviors which are central to this behavioral pattern: length of computer time with general viewing, legal adult pornographic materials, social networking sites, and visiting/interacting with other likeminded persons regarding their sexual interests. However, increased risk (online offending which progresses or used in concert to physical sex offending) would need more intensive treatment focusing on both dynamics of online and direct contact offending.

SOLUTIONS AND RECOMENDATIONS

Law enforcement agencies in the U.S. have taken a very active role in combating Internet crimes against children, and it has been estimated that 95% of their criminal cases involving these offenses result in guilty pleas or convictions (Wolak, Finkelhor, & Mitchell, 2009). In 2009, U.S. law enforcement agencies made an estimated 8,194 arrests for technologically-facilitated child sexual

exploitation offenses (Wolak et al., 2012b). The most common offenses are those related to child pornography, with approximately 5,000 arrests for child pornography possession in 2009 (Wolak et al., 2012a). Law agencies are becoming more aggressive in trying to locate child pornography offenders. This includes officers posing as fellow “traders” in proactive investigations, as well as tracking suspects through peer-to-peer file sharing services. This has resulted in a progressive increase in the number of child pornography arrests since 2000. On the other hand, arrests of offenders who solicit undercover police officers posing as minors have been decreasing in recent years (Wolak et al., 2012b). There are two possible explanations for this decline. First, resources used for proactive investigations have been shifted to child pornography offenders. Second, the extensive media coverage has raised public awareness about online solicitation of minors and has possibly deterred some adult men from engaging in this conduct.

One of the most popular theories in criminology, routine activities theory (Cohen & Felson, 1979), provides a useful framework to address strategies to prevent these offenses. According to this theory, crime is a function of everyday life, and it occurs when three factors simultaneously converge. The first factor is motivated offenders. These are individuals who are seeking a criminal opportunity. Victimization risks are considered a function of an individual’s exposure to offenders (Mustaine & Tewksbury 2000). The second factor is attractive targets. These are individual targets that are appealing to offenders --- whether it is a vulnerable individual or something worth stealing. The final factor is a lack of capable guardians—people who can discourage an offense from happening (Felson, 2001). Individuals can also exercise personal guardianship to prevent their own victimization. Proactive police investigations designed to catch individuals involved with child pornography or solicitation is one way to try and curb the presence of motivated offenders. Furthermore, prevention efforts should be targeted at children and adolescents to increase their levels

of personal guardianship. There is a need for developmentally appropriate prevention strategies that target high-risk behaviors (e.g., visiting chat rooms, corresponding with strangers, and discussing sexual matters online). Some examples include teaching children avoidance skills and educating adolescents about the problematic (and criminal) nature of sexual relationships with adults (Wolak et al., 2008).

CONCLUSION

As technology advanced, so did the opportunities for the exploitation of children. Internet crimes against children constitute a serious albeit misunderstood problem. Child pornography is now a worldwide problem with horrific consequences for victims. The adults who are involved with this material often represent a very serious threat to society. The online solicitation of minors is another contemporary problem. However, the majority of these cases are consistent with statutory rape. Proactive police investigations, particularly into child pornography, are an especially valuable asset in reducing Internet crimes against children. Moreover, realistic prevention strategies offer promise in further reducing online victimization. As technology continues to expand with handheld personal communication devices such as cellular phones, opportunities for sex offenses against minors will also expand. It is essential that society be aware of these possibilities, and be ready to act in an adaptable fashion to prevent the victimization of children and adolescents.

FUTURE RESEARCH DIRECTIONS

Since Internet crimes against children are a new phenomenon, research on this topic is in its infancy. There appear to be two especially compelling directions for future research. First, it will be important to know the relative risk of future contact offending for adults arrested for soliciting

minors online. Second, research should focus on determining which specific strategies are effective in controlling these offenses and preventing victimization of minors online.

KEY TERMS AND DEFINITIONS

Child Molester: Any adult who engages in any type of sexual contact with an individual legally defined as a child.

Internet-Facilitated Child Sexual Exploitation: Offenses in which Internet technology is utilized for purposes of sexually exploiting minors.

Pedophilia: A psychiatric disorder involving an adult who experiences a primary or exclusive sexual attraction to prepubescent children (13-years-old or younger).

Traders: Individuals who traffic and/or collect child pornography.

Travelers: Individuals who use the Internet attempting to solicit minors for sexual purposes.

INTRODUCTION

The primary center behind this chapter is outline a devoted framework which can store forensic digital data patterns permanently. The issues, challenges, conceptual multilayer framework for developing forensic pattern warehouse for betterment of forensic prediction and forecasting has been discussed. A sequence of phases is involved during the design processes of forensic pattern warehouse and initially, conceptual modeling is one of the significant and the initial phase of forensic pattern warehouse design, because it constructs the solid framework for the next level of phases. In view of high semantic nature, there is a need to take a different approach for forensic pattern warehouse design to accommodate flexibility, isolation, extensibility and robustness. In this way, the context oriented forensic pattern warehouse design is one of the possible ways to manage patterns in a better way. The context of underlying pattern also helps to guide the queries to give more satisfactory result. Moreover, the logical modeling of the pattern warehouse should incorporate a mechanism to properly hierarchized the patterns and able to make sharp isolation among patterns. Furthermore, there is a need to provide additional information in logical modeling with patterns to improve query processing by revealing the sense of the underlying domain of source data.

BACKGROUND

In the mid of the 90s, organizations have started to recognize the strategic use of databases as a new discipline which was entirely different from theme of operational database (Tiwari V. at al 2010). Traditionally, operational database has been used to full fill mission-critical, day to day needs for online transaction processing (Inmon W.H., 2005). Organizations have a variety of computer based data processing system such as financial, making, feedback, attendance, and sales etc. which generate operational data (Agrawal R. & Srikant R. 1994). These kinds of data contain detailed, non-redundant and updated values. Those organizations that have recognized the power of information timely will have huge advantages over their competitors and it leads to design an effective data warehouse strategy (Kimball R. & Ross M. 2011). A data warehouse and data mining have given a platform to recognize the role of information behind successful business and much more. Data warehousing improves the productivity of an expert's decision making though consolidation, conversion, transformation, and integration of scattered data, and represents a trusted view of the enterprise. The data warehouse should not consider as a product rather than it is an environment. The data warehousing is a layered process to construct of information system that helps with

Figure 1. Evolution of database technology

organization in their decision making by giving historical data (Romero et al, 2010)). There are some following reasons that make data warehouse is very special:

- Prompt decision need to be made correctly by analyzing available data.
- Business workers are expert in their domain, not in the computer.
- The amount of data doubles in every one and half year, which create the problem in deep data analysis.
- The required infrastructure cost of development of a data warehouse is continuing to decline.
- Organizations have to take critical decisions based on the entire data rather than using rough estimates based on incomplete data.

In the recent evolution of database technology as depicted in Figure 1, patterns are being managed and maintained by Pattern Warehouse Management System (PWMS). Pattern warehouse is a brand-new concept and little emphasis has been given till date. A pattern warehouse is as attractive as data warehouse as the main repository of an

organization's historical pattern and is optimized for on-demand reporting and analysis (Mohammad R. et al (2009), Bartolini et al, (2003)). By nature, patterns are not persistent. There is a need to execute pattern generating methods when patterns are required. Pattern warehouse is a way to make the patterns persist by storing them permanently and it can be considered as a collection of persistently stored patterns.

In order for someone to be able to exploit these patterns on-demand, an efficient general PWMS is required for handling (storing/processing/retrieving) the patterns. The general means, the system must be able to handle all kinds of patterns. Patterns share some characteristics that make traditional DBMSs unable to represent and manage them. Patterns thus, can be regarded as knowledge units that effectively describe entire subsets of data (in this sense, they are compact) (Tiwari V. & Thakur R.S. 2015b). Patterns can be generated from different application domain so they are very heterogeneous in structures and often, heterogeneous patterns are needed to be managed together. The structure of patterns is required to be investigated for the design of a flexible pattern warehouse management system. Pattern management is an important issue in

many different contexts and domains. The most important contexts in which pattern management is required are business intelligence and data mining. Business intelligence concerns a broad category of applications and technologies for gathering, storing, analyzing, and providing access to data to help enterprises in business decisions.

Moreover, many government and private forensic databases can help to both law enforcement investigators and the scientists who support their work in the lab. Forensic Pattern Warehouse (FPW) is a centralized forensic data repository that integrates forensic data from various transactional, legacy, applications and external sources. The Forensic Pattern warehouse provides an environment that is separate from the operational systems and is completely designed for decision-support, analytical-reporting, ad-hoc queries, and data mining. This isolation and optimization enables queries to be performed without any impact on the daily transactional and operational systems (Tiwari V. & Thakur R.S., 2015c). Benefits with a successful implementation of a forensic pattern warehouse include:

- Enhanced forensic intelligence.
- Increased processing of large and complex queries.
- Forensic intelligence from multiple sources.
- Instant access to forensic pattern (Save Time).
- Enhanced forensic pattern quality and consistency.
- Provide historical forensic pattern intelligence.
- Convert forensic data into actionable form.
- Increase scope of forensic data availability.
- Generates a high ROI (return on investment).
- Provide wide variety of forensic patterns.
- Provide various kinds of trends report.
- Decrease computational cost and increase productivity.

Decision making on forensic data is very crucial. Decisions that affect the strategy and operations of organizations will be based upon credible facts and will be backed up with evidence and actual data (Geradts Z. & Bijhold J, (2002), David L.W. & Andrew J. (2013)). Insights will be gained by using forensic pattern warehouse (FPW) through improved information access. A data warehouse is designed for storing large volumes of data and being able to rapidly query the data but forensic pattern warehouse is designed and constructed with a focus on speed of knowledge retrieval and analysis. Pattern warehouse does not concentrate for creation and modification of forensic data. In contrast, the forensic pattern warehouse is built for analysis and decision making. In conventional ways, forensic data are stored around transactional database and have limited accessibility (Geradts Z. & Bijhold J, (2001), Mikkonen S. & Astikainen T., (1994)). It is almost impossible to any organization to share their transactional databases. There are large amount of forensic data in country but scattered in organization and institute wise. They hardly exchange their forensic data for analysis purpose (Sibert R.W., (1994), Catherine et al. (2016)). The result of any analysis process is directly depends on amount of quality data. Decision making process lies on credibility of analysis. Analysis on single organization's forensic data cannot bring such credibility (Tobias K. et al, 2011). For many organizations, forensic information systems are comprised of multiple subsystems, physically separated and built on different Platforms and formats. Moreover, gathering data from multiple disparate data sources is a common need when conducting forensic data analysis for decision making (John H. et al, 2011). We need to gather forensic data from various small or big organizations time to time and need to put in central repository system (Werrett D.J., 1997). We perform integration of existing disparate data sources and make them accessible in one place. This repository system consisted of same grade (forensic) of data with different formats. These

Figure 2. Layered forensic pattern warehouse framework

technical issues can be covered in preprocessing phase. There is a separate forensic data integration system, known as ETL, within a forensic pattern warehouse environment (Tiwari V. & Thakur R.S. 2015a). This system consolidates forensic data from multiple source systems and transforms the data into a useful format. Further, user of forensic data will be able to query data directly with less information technology support. This allow to users to spend more time performing data analysis and less time gathering data.

MAIN FOCUS

A Multi-Layered Architecture

An elementary model is proposed to develop an overall integrated environment for uniformly representing (create, store and update) and querying various kinds of forensic patterns. A multi-layered architecture is introduced and considered one of the suitable solutions for forensic pattern warehouse management system. The architecture is made up of the number of interconnected layers which include Physical layer, Pattern storage layer and Application layer as depicted in Figure 2.

Physical Layer

Bottom of the architecture depicts the data store that contains the raw data. Raw data can be either managed by a DBMS (Database Management System) or can be stored in files, streams or any other external physical data source. External data sources are operational systems/flat files/ text files, etc., used to manage the data to support critical operations and relatively small number of well-defined business transactions (Golfarelli M. & Rizzi S., 2009).

Pattern Storage Layer

The middle layer contains patterns, which forms the core part of the pattern warehouse management system. The pattern stored in the pattern warehouse is uploaded by pattern interface. This layer can be further divided into Pattern-Tier and Context-Tier.

- **Pattern-Tier:** This is populated with patterns which are extracted through various techniques pushed here from the preceding layer.

- **Context-Tier:** Context gives the ability to organize patterns according the context and helps to give sense about what kind of knowledge they are carrying. It defines schema and procedure to organize patterns contextually. It holds built-in and user defined types for patterns and also it describes the syntax of the patterns.

Collectively, pattern tier and context tier form the pattern warehouse where patterns, trends, and knowledge reside. Pattern warehouse is the core of the pattern warehouse management system and it can think as a logical and compact representation of processed and mined data.

Application Layer

The top of the architecture consists application layer. This is the representation of other applications, machines, users, etc. The application layer of the pattern management architecture is the layer to the end-user deals with directly. This layer also includes the hardware and software involved in displaying and presentation of patterns.

Pattern Representation

The following section covers are various ways to define and declare the forensic patterns to keep the sematic of patterns and forensic data intact (Manolis T. & Panos V. (2003), Rizzi, S. et al (2003)).

Patterns are represented with triple (Pattern_Type, Pattern, Class).

Pattern_Type: A pattern type '*pt*' is a quintuple -

$$pt = (n, ss, ds, ms, f)$$

Where:

n is the name of pattern type.

ss (structure schema) is a definition of pattern space.

ds (source schema) define related raw data space.

ms (measure schema) quantify the quality

f is a function that describes the relationship between source space and pattern space.

Pattern: Let $pt = (n, ss, ds, ms, f)$ be a pattern type.

A pattern '*p*' instance of '*pt*' is a quintuple:

$$P = (pi, s, d, m, e)$$

Where:

pid- pattern identifier

s- is a value for type '*ss*'

d- dataset

m- is a value of type *ms*

e- region of the source space

Example of a pattern of association type is:

pid: 001

s: (head = { 'Thumb_Finger_Print' }, body = { 'Knife', 'Minor_Age' })

d: 'SELECT SETOF record FROM

minor_age_prison_db GROUP BY recordID

m: (confidence = 0.75, support = 0.30)

e: { transaction: { 'Thumb_Finger_Print', 'Knife', 'Minor_Age' } }

In this chapter, the attention is given on the central issues: conceptual and logical schema design only. In the view, Figure 3 depicts very abstract the conceptual view of forensic pattern warehousing including data sources, patterns, type and pattern warehouse. There is not found context based conceptual and logical schema. The conceptual modeling of pattern warehouse is with clear goals and objectives, such as completeness (all kinds of patterns), summarizability (ability to compute aggregate or derived pattern), and knowledge Independence (every pattern can be answered using the pattern warehouse only) as constraints (Tiwari V. & Thakur R.S. 2015b).

Figure 3. An abstract conceptual view of pattern warehousing

FUTURE RESEARCH DIRECTIONS

The presented work covers conceptual the forensic pattern warehouse while discussion on physical modeling is missing. Future work includes the dynamics of changing, modifying and updating of forensic patterns in warehouse. We must address the pattern's storage technology and schema toward quantity, quality and heterogeneity. There are also need to explore about duplication, compression, optimization and pattern placement. Forensic pattern warehouse refreshment problem is very important to handle carefully.

CONCLUSION

An elementary model is proposed to develop an overall integrated environment for uniformly representing (create, store and update) and querying various kinds of forensic patterns. A multi-layered architecture is introduced and considered one of the suitable solutions for pattern warehouse management system. The architecture is made up of the number of interconnected layers which include Physical layer, Pattern storage layer and Application layer. In presented model, each layer

is proposed to perform concise and specific task. The model has enough flexibility and extensibility to use its own way. This allows the user to: 1) use standard pattern types or define new ones; 2) generate patterns and represented according to existing standards; 3) allow using new standards and mapping.

KEY TERMS AND DEFINITIONS

Business Intelligence: The process, technologies, and tools needed to turn data, patterns into information, information into knowledge, and knowledge into plans that help for forensic decisions.

Data Acquisition: It is a processes used to collect information to document or analyze some phenomenon.

Data Mining: It is the practice of analyzing, examining data from different perspectives and summarizing to generate new information.

Forensic Data Analysis (FDA): It is the process of using of controlled and documented analytical and investigative techniques to identify, collect, examine, and preserve digital information.

Heterogeneous Pattern: Pattern with different structure.

Pattern Warehouse Management System (PWMS): Pattern management system used to model, store, retrieve, and manipulate patterns in an efficient and effective way.

Pattern: It is a compact and rich in semantic representation of raw data.

Pattern-Warehouse: It is a collection of persistently stored patterns.

Uncovering Limitations of E01 Self-Verifying Files

Jan Krasniewicz

Birmingham City University, UK

Sharon A. Cox

Birmingham City University, UK

INTRODUCTION

Teaching good practice in computer forensics is important to understand the correct operation and limitations of computer forensic hardware and software. One task is to demonstrate the self-verification feature of evidence file formats such as the EnCase E01 file format that contains an image of acquired data. The E01 file contains the data plus extra data in the form of hash values and Cyclic Redundancy Check (CRC) values used by computer forensic software to check the data contained within the file has not been tampered with. Students are taught how to carry out this task and verify the file by making a change to the generated file and observing mismatches between hash values and Cyclic Redundancy Check (CRC) values generated when the data was copied and when the file is loaded into computer forensic software. Whilst creating teaching materials for students to carry out this task an anomaly was identified in one of the forensic file formats, the E01 format, commonly used by practitioners. The anomaly allows changes to be made to certain bytes within the file that are not detected by computer forensic software when verified by the associated hash and CRC values. This paper describes the anomaly in the file format, discussed the implications for relying on the self-verification feature of the E01 file format and concludes on methods to make any change to the file contents detectable.

Background

One of the first tasks before conducting a computer forensic analysis of data is to make a forensically sound copy of the data stored on, for example, a hard disk drive. This task forms the acquisition stage of an investigation. By “forensically sound” it is meant that the copying process does not alter the source data resulting in an exact copy of the data (Casey, 2007). This task involves making a bit-for-bit copy of the data and using a method that assists in determining the integrity of the resulting copy as part of the chain of custody.

It is important to be able to determine that the copy of data has not been changed before it is analysed. It is common practice and recommended by organisations such as the Association of Chief Police Officers (ACPO) and National Institute of Standards and Technology (NIST) to use a mathematical function to calculate a unique value for the data at the time of copying. Examples of mathematical functions used to check the integrity of data are Cyclic Redundancy Check (CRC) and cryptographic hash (Schneier, 1996). These functions are implemented in computer programs to compute a value from a computer file or entire contents of a storage device. The value is recorded so that whenever the digital evidence is analysed the value is recomputed and compared to the original value.

Computer programs have been developed to automate the copying process and calculate the integrity values for the acquired data. These values are stored within the resulting copy of the data. Storing the integrity values within the file allows the copy to be *self-verifying* when analysed with computer forensic software. When the copy is used by a computer forensic software application, such as Guidance Software's EnCase and AccessData's FTK, the application recalculates the unique value and then compares it with the value stored in the file. The program displays a warning message when the original and calculated values are different as this difference indicates the file has changed, the change could be as a result of corruption or it could be more sinister due to a deliberate change by an individual.

This paper considers the integrity values stored in the copy of the data, commonly known as the image file or digital evidence container file (Common Digital Evidence Storage Format Working Group, 2006). The paper describes mathematical functions used to calculate the integrity values and how the property of the function allows data to be validated. The paper then describes how a practical exercise to demonstrate self-verification features to students identified an anomaly where it was possible to change a byte within the file without the self-verification detecting that the copy had been changed. The paper explains why additional integrity values should be calculated based on the entire data, copy and integrity values combined, to further enhance confidence the copy has not been altered after it has been made.

Hash Functions in Computer Forensics

Hash functions are one approach to solving the problem in computer systems of being able to perform a fast lookup of data in a data store such as RAM or disk drive (Knuth, 1998). The hash function takes as input a characteristic or characteristics of data and computes a value based on the characteristic. This value is used to locate

the data within a data store, for example. When a program needs to find data within a set of data the hash value is calculated and the value used to examine a location in the data store for the presence of that data. As a result, the hash value offers almost direct access to the data.

In comparison algorithms such as linear search are slow as it involves examining each data location for the presence of a specific data value from the first to the last. The amount of time to find data in the data store using a linear search is proportional to the number of data items in the data store and as the number of items increases so does the time to search the data store. The advantage of the hash function is it computes a hash value in constant time irrespective of the location of the data in the data store. Consider the example of searching for an individual's personal details based on some identifying data within a data store comprising of 1,000,000 individuals. A linear approach would inspect every location until a match is found where the time take to find the data is proportional to the amount of data, more data results in a longer search, potentially. A hash function would be applied to the identifying data and a value calculated that is then used to access a location directly.

Ideally hash values calculated are unique for different data but for some applications this is not entirely a requirement (Knuth 1998). Computer forensics make use of hash functions but a specific type called cryptographic hash functions that are designed to produce unique values for data. This property of calculating a unique value allows the value to be considered as a digital signature or fingerprint of the data allowing for data to be found by its hash value or verified because its value is unique (Cowen, 2013).

Cryptographic hash functions are used for the validation of arbitrary messages (the data) between individuals (Schneier, 1996). A key property of cryptographic hash algorithms is that they permit the verification of arbitrary streams of data by producing a unique value for that message exactly. In the case of cryptographic hash functions like

MD5 (Rivest, 1992) and SHA1 (RFC3174), they are designed to produce a different value when there is a small change to the message such as the changing of one bit. This property of cryptographic hash functions allows an individual to check the integrity of the data before use. The MD5 function produces a 128bit value from a data stream of any length, for example an individual file or contents of an entire storage device, where this value is unique to the data theoretically. The uniqueness of MD5 is that there is a 1 in 2^{128} or 1 in 3.4028236692093846346337460743177x10³⁸ chance of two streams of data producing the same MD5 hash value even when the difference between the two streams is one bit and the stream of bits is many millions of bits. The SHA-1 function calculates a 160 bit value where the chances of two different data producing the same value is 2^{160} or 1 in 1.4615016373309029182036848327163x10⁴⁸. However there is the issue of collisions in cryptographic hash functions where a collision occurs when two different messages produce the same hash value (Sotirov et al., 2011). Collisions present a problem as a malicious data could be constructed to generate a hash value with the same value as valid data (sKyWIper Analysis Team, 2012). Thomson (2005) discusses the implications for collisions and birthday attacks to computer forensics and concludes that whilst there are problems with MD5 collisions they can be overcome by using alternative algorithms. There have been a number of legal challenges to Encase regarding the verification process as covered in (Encase, 2014) where Encase 6 was augmented the Secure Hash Algorithm (SHA1) to provide an additional means to verify the data contained in an E01 file.

Further properties of cryptographic hash functions are that (Schneier, 1996):

- It is easy to compute the hash value for any message.
- It is difficult to compute the message from the hash value.

- It is difficult to determine another message that produces the same hash value of the message.

This latter property gives the function the property of being collision resistant where it should not be easy to compute another message that results in the same hash value. If this should happen then it would be easy to substitute one message with another without being detected. Examples of cryptographic hash functions are Message Digest (MD), Secure Hash Algorithm (SHA) and RACE Integrity Primitives Evaluation Message Digest (RIPE-MD) (Schneier, 1996). These properties of cryptographic hash functions are significant to computer forensics as they allow data to be verified after acquisition by calculating and comparing hash values.

MD5 and SHA1 functions are implemented in computer programs that are used to make the copy of the data, examples of which are AccessData's FTK Imager and EnCase. There have been some concerns with using MD5 and SHA-1 (Wang, Yin and Yu, 2005) as attacks on the algorithms have demonstrated that it is possible to generate the same value for different data. However it is acceptable and standard practice to use MD5 and SHA-1 in a legal court (Guidance Software, 2009).

As well as using cryptographic hash functions to verify the overall integrity of the data, the CRC function is used to calculate values for blocks of acquired data and stored in the digital evidence file. The CRC value's properties are that it allows data to be checked for errors where CRC is used to check packets of data communicated over a network (Halsall, 1995). A CRC value is calculated for a block of data and transmitted over the network with the data. The receiver performs the CRC check only on the received data and compares with the received CRC value. If the CRC values are the same then this means no errors have been introduced into the data as a result of transmission. If the CRC values are different then this means there are errors in the data due to transmission and

the receiver would request retransmission of the data. CRC function has similar properties to the hash function but it does not generate a unique value for data only a value that allows the data to be verified. CRC is used in digital evidence files to validate smaller blocks, for example 64 sectors worth of data (Bunting, 2012), within the data so should there be a hash mismatch a program can identify a location within the file.

It is important to note CRC and cryptographic hash functions cannot verify the data acquired are correct; they only assist in determining acquisition produced an exact copy of the original data. As a result any existing corruption in the data or successful attempts to wipe the data cannot be identified with cryptographic functions or CRC.

Concentrating on cryptographic hash functions, the hash value generated at acquisition and then the hash value generated when the data are verified are called the acquisition and verification hash values, respectively (Bunting, 2012). When the acquisition and verification hash values are the same then the data in the file are understood to be consistent with the original data copied from the device. Issues about the acquisition process are outside the scope of this paper. This paper assumes that the process of acquisition is correct and that a valid evidence file has been produced. When the values are different this means there has been some alteration of the evidence file contents. For example, it may be the case that the device the evidence file is stored on has some hardware fault corrupting the file. It could be that person or persons unknown have tried to tamper with the file by using a hex editor to modify key bytes in the file. In both cases the CRC and hash values help in determining that corruption has occurred and

where this corruption affects the acquired data, for example corruption in the file corresponds to specific sectors. This self-verification property of the evidence file format allows it to be forensically sound.

Evidence File Formats

The inclusion of extra data to allow the digital evidence file to be validated automatically has resulted in a number of evidence file formats (Common Digital Evidence Storage Format Working Group, 2006). The primary objectives of evidence file formats are to be an accurate copy of the original data and allow for corruption and/or alteration of the contents to be detected. Unlike other file formats evidence file formats cannot be updated with new data; they are effectively sealed. Should an error in the creation of the evidence file occur for example, incorrectly selecting source devices and data were not copied, then, the entire process has to be repeated to create a new file.

Examples of evidence file formats are Access Data's Advanced Forensic Format (AFF), Guidance Software's E01 format and ASR Data's SMART format. These file formats all make a binary copy of data and use CRC and cryptographic hash values to validate the data. The evidence file format used for the exercise is the E01 evidence file format described below.

The E01 Evidence File Format

The E01 format is used by a number of computer forensic software such as Guidance Software's EnCase and AccessData's FTK. The logical structure of the E01 format is shown in Figure 1.

Figure 1. The logical structure of the E01 evidence file format (source: Bunting 2012)

The evidence file is generated at acquisition time by a computer program called an imager (Casey, 2009). The Header stores details of the acquisition such as a case name, evidence number, examiner name and brief notes. The Data Blocks in Figure 1 are regions containing the binary copies of the acquired data. A CRC value calculated for the Header and Data Block is stored in the file at creation. The purpose of the CRC values is for performing an integrity check on the Data Blocks and Header separately. As a software application loads the data from the file it recalculates the CRC value based on the data in the block and compares it to the stored CRC value identifying any corruption in the data block.

At the end of the file is the MD5 cryptographic hash value. This is calculated only on the acquired data and does not include the header and CRC values stored in the file. The E01 file format now includes a SHA-1 hash value (not shown in Figure 1) that is also calculated on only the acquired data and stored at the end of the file. The purpose of this additional hash is to provide a second way to check integrity using a different function to calculate hash and therefore having two values to compare against. The inclusion of the SHA-1 value helps with mitigating claims about the reliability of the MD5 algorithm to produce unique values for different data and discussed in section 2 of this paper. In combination, CRC values determine if there has been corruption in a data block and the cryptographic hash function values determine if there is corruption in the entire acquired data. This combination addresses the smaller (in terms of number of bits) CRC value where there is a greater possibility of corruption producing the correct CRC value and, hence, the corruption not being detected.

When an evidence file is loaded into computer forensic software the software begins recalculating CRC and cryptographic hashes based on the acquired data. Once the software completes recalculating the values it compares the CRC and hashes calculated with the CRC and hashes in the file. The software displays an error message

indicating a mismatch when the cryptographic hash values, acquisition and verification, do not match and an examiner can find out which data blocks are in error.

It is good computer forensic practice to check these values before conducting an analysis on the data as results based on an invalid data could be called into question. Students on a BSc Forensic Computing complete a practical exercise on verifying a digital evidence file and see the value self-validating evidence file formats by making a change to the file to produce a mismatch between acquisition and verification hashes. The exercise is described in the following section.

File Verification Exercise

One of the initial exercises students on a BSc Forensic Computing course do is to validate an evidence file and gain experience to determine whether a file is valid or not. The exercise comprises of two parts. Part one requires students to load the test evidence file into computer forensic software and wait for verification to complete. They then check the acquisition and verifications hash values displayed by the program are the same or what message the program should display when the verification has been completed without mismatch.

The second part involves students using a hex editor program to load and view the binary contents of the evidence file. They are instructed to change a byte at a location within the file from its current value to a different value. The file is saved and reloaded into computer forensic software for validation where students are instructed to check the acquisition and verification hash values are different as a result of the change. The hash values themselves are not of significance to the exercise but the fact they are different is significant as it indicates a problem in the integrity of the file.

The location of the byte to be changed in the second part of the exercise was determined by obtaining the logical size of the file and dividing by two to be the approximate mid-point. The total

Figure 2. Location of byte to be changed for the exercise showing the original value

size of the evidence file is 1,960,680 bytes and for simplicity the byte at 980340 was to be changed by students from its original value to 0xFF. The choice of the value 0xFF was arbitrary based on the assumption any change in the value whether it was a minor or major change should result in a verification error. A minor change would be to calculate the binary value for the byte value stored at the location and change one bit, for example the original value is D0 in the hexadecimal number system. The binary value for D0 is 11010000 where changing the right most bit that is the least significant in the number results in 11010001 or D1. A major change is to change many bits to result in a significantly different number such as reverse the binary value from 11010000 to 00101111. FF was chosen as this results in the binary pattern

11111111 with 5 bits changed. Figure 2 shows the location and original value stored at that location.

The value at the location D0 was overwritten with the value FF as shown in Figure 3.

RESULTS

The exercise was conducted by the tutor in order to check that the exercise would produce the mismatch for the second part of the exercise. The file was saved and loaded into the EnCase computer forensic software where the expected result from the program was that there is a verification error due to the calculated hash values being different. However, the actual result was that the program completed the verification successfully with no

Figure 3. Location of byte after being changed to FF

verification errors indicated. The EnCase function to verify file integrity was invoked explicitly where the same result of no verification errors was received. Figure 4 shows the results of verifying the file's integrity.

This result was not expected and the test was repeated by loading the evidence file into another computer forensic program AccessData's FTK Imager that performs a verification check using the same MD5 and SHA-1 cryptographic hash functions. The experiment was repeated to identify if the problem was specific to EnCase. On completing verification FTK Imager also displayed no difference in the computed verification hash values and they match. Figure 5 shows the results of verifying the file's integrity using the FTK Imager program. The conclusion based

on this result alone is that the values, CRC and hash, stored have not been sufficient to allow the program to detect a change in the evidence file itself. The CRC and hash values are computed solely for the acquired data not the evidence file per se. As a result changes to data outside the data blocks, CRC and hash value are susceptible to change without detection.

DISCUSSION OF RESULTS

The results in the previous section suggest that a byte can be changed in an E01 evidence file without resulting in an error being detected when the file is verified automatically by computer forensic software such as EnCase and FTK Imager. This

Figure 4. Modified file verification of modified showing no errors

result was unexpected given the claims that E01 files are self-verifying and changes to the file are detected through the use of CRC and hash values embedded in the evidence file. As a result the self-verification hash values and CRC should only be considered as validating the acquired data and not the entire file. Based on the E01's specification a mismatch should occur when a byte has changed, as that change will either be in a data block and identified by the hash value and CRC as expected. Alternatively the change should be detected because it occurred in a CRC or hash value because these data are the only other data in the file. The change results in an invalid CRC or hash value in the E01 file and results in a verification error because the CRC and hash calculated from the data block will be different. It would appear

there is at least one location in the file that can be changed without being detected using the file's self-verification feature.

Confirming the integrity of the entire E01 file is achievable by calculating the hash value for the entire image file after it has been created. This would be consistent with computer forensic practices of using hashes to confirm data integrity (Kumar et al. 2012).

This result calls into question relying purely on the self-verification of the E01 evidence file format to verify the data. A similar problem occurred when a legal challenge to the E01 file format was made due to the use of MD5 hash function used to verify the data. The challenge was made based on academic research that demonstrated it was possible to generate the same hash value for

Figure 5. Verification results produced by the FTK Imager program on the modified file.

two different data (Boer and Bosselaers, 1994). The challenge was successfully countered and where an additional hash value was used in the file to further improve data integrity (Guidance Software, 2009).

Likewise the results presented in this paper show a problem in self-verification property of the E01 file format for the whole file but significance of the result to the E01 file format may not be major. Further work is needed to confirm this assertion that the change made to a file was at a location that was not in a data block, CRC or hash value.

A solution to relying on the internal hash and CRC values is to use hash function such as the MD5 and SHA-1 to calculate the hash value for the E01 file as a whole, header, data blocks, CRC values and hash values. The E01 file hash value would be calculated immediately after acquisition was

completed and a record made of the hash value. The hash value is recalculated whenever the E01 file is to be used in an analysis and the calculated hash value compared with the original hash. The result of the comparison would verify the file's integrity or indicate there has been some change to the file after acquisition. This check could be performed manually by using a program such as the one above to calculate hash values. Alternatively the E01 file can be augmented to include extra hash values for validating the file.

CONCLUSION

The primary conclusion of this paper is that is possible to make a change to a E01 evidence without that change being detected though the self-verification feature of the file format. This

result contradicts the accepted fact that E01 files are self-verifying and can detect the changes to the file. A more correct interpretation is the verification feature of E01 files detects changes that have occurred only within data blocks acquired. As a result confidence in the E01 file format to be forensically sound with regards to verifying the data in contains is maintained. However the same is not true for verifying the E01 file in its entirety.

The recommendation of this paper is that to verify the integrity of the entire E01 file an additional hash value using an accepted hash function such as MD5 or SHA-1 or both is calculated and recorded as part of good practice. This hash value is calculated at the same time the image file is created. Whenever the E01 file is to be used the hash value is recalculated on the entire image file and compared with the original hash. When the values are the same it can be taken that the E01 file has integrity and can be used. When the values are different then there is some doubt over the integrity of the file irrespective of the CRC and hash values embedded in the E01 file.

FUTURE RESEARCH DIRECTIONS

Further work is needed to identify whether the anomaly identified in an E01 file is specific to the test file or it can be consistently produced for other E01 files of differing sizes (in bytes) and for split E01 files. This further work will also involve changing bytes at other locations in an E01 file in order to ascertain whether the acquired data has been changed but the change not detected during self-verification as described previously. In addition other evidence file formats will be tested as well as using alternative programs such as hashmyfiles.

The secondary conclusion is the importance of testing computer forensic hardware and software and associated artefacts in computer forensic teaching. Testing helps students understand using

hardware and software in order to build confidence in what the hardware and software does and its correct operation. It also helps with emphasising the need for a rigorous testing in order to demonstrate procedures are correct to ensure evidence is admissible.

KEY TERMS AND DEFINITIONS

Acquisition: The process by which data is acquired from a storage device and stored in an image file.

Bit-for-Bit Copy: A bit level copy of an arbitrary stream of data.

Cyclic Redundancy Check: An algorithm that computes a value for a data stream to use used for error detection and possible correction.

E01: A type of image file format that includes a bit-for-bit copy of source data plus hash values calculated from the original data.

Image File: A file containing acquired from a storage device.

MD5: A type of hashing algorithm that computes a fixed size value for an arbitrary data stream.

Verification: The process by which an image file is verified before use. Involves comparing hash values computed when the image file was made and when it is loaded into computer forensic software. Any discrepancy between the hash values suggests tampering or corrupting of the data within the image file.

Crisis Response and Management

Crisis Response and Management

Sergey V. Zykov

National Research University Higher School of Economics, Russia

INTRODUCTION

In the 1960s, the so-called “software crisis” triggered the advent of software engineering as a discipline. This term originated from the critical development complexity, which happened due to the rapid growth of computational power. At that time, the computing power of the machines became so overwhelming that a number of software development projects were over budget, late or unsuccessful. One well-known example was the first General Electric’s payroll system launched in 1954 at Louisville, Kentucky; this was late, over budget, and missing crucial features (Topi, & Tucker, 2014). Irrespective of human efforts, the complexity of the hardware and software systems was hard to cope with by means of the old methods and techniques. The challenge was so dramatic that in 1967 NATO arranged an invitation-only conference, where world leaders in IT research and practice searched for an efficient response. At the conference, the term “software crisis” was coined by F.Bauer and used by E.Dijkstra (Naur, & Randell, 1968).

Another term suggested at the conference by the same F. Bauer was software engineering. The idea was to apply the engineering methods of material production to the new domain of large-scale concurrent software systems in order to make the software projects more accurate and predictable. This software engineering approach was feasible, though the methods and practices used had to differ substantially from those used in the material production. Specifically, the experts examined bridges as the instances of complex material systems.

The attendees concluded that the distribution of time and cost by the lifecycle phases, especially for

the post-delivery maintenance was very different for software and material production. This is why the new software engineering discipline was in need of new methodologies, techniques and tools.

The focus of the software engineering discipline was the “serial” production of substantially large-scale, complex and high quality software systems. Concerning software complexity, at least two dimensions were identified; these were technical and management complexity (Booch, 2006). To measure software product complexity and quality, a set of attributes and metrics was suggested. The quality attributes included performance, reliability, security, fault tolerance, usability, strategic reusability and maintainability; their importance depended on the product size and scope (Lattanze, 2008). The complexity metrics included product size in terms of lines of code, function points, nesting levels, cyclomatic complexity and a number of more sophisticated ones (Debbarma, Debbarma, Chakma, & Jamatia, 2013). These metrics assisted in the divide-and-conquer strategy; later, they this general approach transformed into elaborate product estimation techniques and software development methodologies (Jensen, 2014).

Researchers argue whether the crisis in software engineering is over yet (Colburn, Hsieh, Kehrt, & Kimball, 2008) or it still exists (Buettner, Dai, Pongnumkul, & Prasad, 2015). This happens because of the fundamental differences in the lifecycles of software and material products. One critical difference between large-scale software and material production is the distribution of time and cost by the development lifecycle phases. Therewith, maintenance is the most time and cost consuming, it often exceeds 60% of the software project expenses (Schach, 2011). The other crucial difference is that

DOI: 10.4018/978-1-5225-2255-3.ch120

software production often depends dramatically upon human factors. These human factors relate to the management aspects of software complexity, whereas the technology factors relate to the technological aspects. Certain product categories are far more complex in terms of management than in terms of technology; however, the influence of the human factors on their development is largely underestimated. For such software product categories as enterprise information systems and defense management information systems, neglecting these human factors often results in project delays or even failures (Booch, 2006).

Therewith, the software crisis originates from a number of factors; these are human-related and technology-related factors. To manage this crisis, the authors suggest a set of software engineering methods, which systematically optimize the lifecycles for both types of these influencing factors. This lifecycle optimization strategy includes crisis-responsive methodologies, system-level architectural patterns, informing process frameworks, and a set of knowledge transfer principles (Zykov, 2009; Zykov, Shapkin, Kazantsev, & Roslovtshev, 2015; Zykov, 2015).

Software development usually involves customers, developers and their management; each of these parties has different preferences and expectations. Therewith, these parties often differ in their vision of the resulting product; typically, the customers focus on business value while the developers are concerned with technological aspects. Such a difference in focus often results in crises. Thus, the software crises often has a human factor-related root cause. To deal with these kind of crises, software engineers should enhance their skillset with managerial skills, such as teamwork, communications, negotiations, and risk management.

BACKGROUND

In the 1960s, the software production lifecycle was unstable as no systematic approach existed.

At that time, software development did not allow for adequate planning and management of a project timeline and budget. The software products were unique masterpieces; they used a build-and-fix approach as the core “methodology”. A systematic approach to product lifecycle was required in order to manage this crisis of development. This approach was to include certain technical and management aspects. The technical aspects should include justified architecture selection and high-level design. The management aspects should include teamwork and transparent communication between the client and the developer.

In this period, software development involved a number of parties with significant differences in goals and expectations. These were clients, developers and their management. Each side usually had a different understanding of the future product, as the clients were business oriented, while the developers focused on technology.

At present, this same lack of common understanding hampers software development; it is a possible source of a software crisis resulting from management complexity. To deal with this kind of crisis, software engineers enhance their technical abilities by a specific “soft” skillset. This includes collaborative teamwork, risk management, communications and negotiations. The “soft” skills assist software engineers in their management of the present-day software development crisis, which often results from human factors.

The following decades of the 1970s and 1980s changed software development from an art to a science, though it had not yet become a serial production technology. Techniques and methods appeared which are currently known as the Programmer’s Workbench (Dolotta, & Mashey, 1976), third-generation programming languages and the supporting Structured Analysis and Design Technique (Dahl, Dijkstra, & Hoare, 1972). Further, in the 1990s software development technologies became even more advanced. The new technologies which arose at that time were more process focused; a few examples of these include OOAD (Jacobson, Christerson,

Jonsson, & Overgaard, 1992) and the capability maturity models of CMM and CMM(I) (Paulk, Curtis, Chrissis, & Weber, 1993; Linden, 1994). Major software R&D centers appeared, such as the Software Engineering Institute (<http://www.sei.cmu.edu>). A number of mission-critical systems (i.e. essential to the organization survival) appeared. Relative value of software increased. Software estimating tools and methods appeared, which made software development more crisis-responsive and better manageable (Jensen, 2014). A few examples of these methods are: COCOMO and COCOMO II (Boehm, 1981; Boehm, Egyed, Clark, Horowitz, Westland, Madachy, & Selby, 1995), Price-S (Park, 1990), Sage (Jensen, 2007), and Seer (Jensen, 1980). However, the crisis in software engineering lasted longer and was deeper than that in material manufacturing. One possible reason for this is that human-related factors are much more complex in their nature and harder to manage (Jensen, 2014).

Absence of a universal software development methodology indicates that certain consequences of the crisis persist. To manage the crisis, life-cycle optimization is required. This optimization should systematically address crisis technological and management aspects by means of software engineering models, methods, tools, techniques and practices.

Any software architecture has multiple perspectives. These include process, data and system interfaces (Lattanze, 2008). Any single-perspective software architecting, or even a two-“dimensional” one, usually results in insufficient crisis agility. The present-day crisis manifests itself in high turbulence and fluctuating customer demand. Inefficient clients with excessive overheads often end up with dramatic profit losses. In crisis, the software architecture often requires extending beyond the traditional software engineering of “heavy” methodologies, such as Rational Unified Process (Kruchten, & Kroll, 2003) or Microsoft Solution Framework (Turner, 2006). Human factor-responsive software development methodologies, such as Agile (Agile Manifesto, 2001),

Scrum (Takeuchi, & Nonaka, 1986) or Extreme Programming (Beck, & Andres, 2004) can often better assist in crisis management.

TECHNOLOGY-BASED CRISIS RESPONSIVE SOFTWARE DEVELOPMENT

Issues related to software and hardware system development tend to become more essential in a crisis. A positive solution is to create uniform architectural patterns for such complex systems (Zykov, 2010).

Crisis-responsive software engineering uses general principles of architecture, such as components and connectors (Lattanze, 2008). Top-level architectural design is critical; it determines key concepts and interfaces for the subsystems of software products to be developed/optimized. At this level, high-level patterns are applicable, which describe the interfaces for the software system components. E. Gamma laid the foundations of the software design patterns (Gamma, Helm, Johnson, & Vlissides, 1998), which are applicable to large-scale software systems (Fowler, 2002; Freeman, Bates, Sierra, & Robson, 2004; Zykov, 2009).

However, each instance of the patterns is dependent upon both the problem domain and the nature of the client. That is why the authors suggest adding human factor-based patterns to the technological and architectural ones (Zykov, 2009). In crisis, both components may critically influence software development. Therefore, human factor issues often manifest themselves in undisciplined development and communication problems.

In a crisis, the technological factors that influence software development have three architectural perspectives: business process perspective, data flow perspective, and system interface perspective. Each of these three perspectives should be projected to the business management levels, which include everyday management, short-term planning and strategic decision-making. The

combination of these architectural perspectives and the business management levels results in the crisis agility matrix. As such, crisis agility should be understood, interpreted and measured in terms of mission-critical crisis quality attributes, such as portability, maintainability and adaptability. To design a crisis-agile software system, architects should plan for its decomposability to smaller subsystems and future reengineering (Zykov, Shapkin, Kazantsev, & Roslovtsev, 2015).

The crisis agility matrix allows the identification of technology and human factor-related mission critical dependencies for the software systemic properties. These dependencies suggest a set of constraints which guard the system development process from potential analysis and design errors. This set of constraints warns of potential architectural problems, challenges or risks represented in terms of contradictions between the business processes, data flows and system interfaces. The matrix allows for crisis responsiveness estimation in terms of process management, data integrity and interface quality (Zykov, Shapkin, Kazantsev, & Roslovtsev, 2015).

An enhancement for the agility matrix is a pattern-based crisis-responsive methodology of software development. This methodology extracts common enterprise software patterns of module level and applies them to a series of heterogeneous implementations. The approach extends the spiral lifecycle (Boehm, 1986) by formal models for data representation and management, and by development tools based on domain specific languages (Hohpe, & Woolf, 2004). Implementations include oil and gas resource planning, airline dispatching and nuclear power plant construction support (Zykov, 2010).

CRISIS-RESPONSIVE ARCHITECTURE FOR MISSION- CRITICAL SYSTEMS

Mission-critical software systems usually include subsystems of different levels. The higher levels

assist in decision-making and long-term planning; the lower ones support data acquisition hardware. Different levels serve the information requests of different groups of users, such as top and middle management, analysts and designers. Thus, these software levels and their interfaces are human factor dependent.

It is possible to extend the pattern-based approach to software systems development (Gamma, Helm, Johnson, & Vlissides, 1998; Fowler, 2002) for software system engineering; the focus is the pattern of high-level system architecture (Zykov, Shapkin, Kazantsev, & Roslovtsev, 2015).

A crisis-responsive system should have a scalable architecture so that the system supports easy decomposition and reengineering. Typically, a mission-critical system architecture has three perspectives. These three perspectives focus on processes, data and hardware (Lattanze, 2008). An architectural design, which does not support all three perspectives, is usually insufficient for crisis agility. The system lifecycle should consider the dependencies between these three perspectives; for each individual system, it is essential to address these dependencies at the early stages of analysis and design.

The crisis agility matrix includes the three perspectives for processes, data and system interfaces (Zykov, Shapkin, Kazantsev, & Roslovtsev, 2015). The first perspective represents dynamics; it assists in decomposing strategic goals into business processes. The second perspective contains the decomposed data objects for these business processes. The third perspective includes the hardware and software systems, which operate these data.

The system architecture framework incorporates the three perspectives (Zykov, Shapkin, Kazantsev, & Roslovtsev, 2015); it is based on high-level patterns (Fowler, 2002; Freeman, Bates, Sierra, & Robson, 2004; Hohpe, & Woolf, 2004). Each level communicates directly with the adjacent ones; it is the consumer for the lower level and the provider for the higher level.

The top, strategic level represents decision-making and business intelligence. This level analyses and aggregates data from the software for planning enterprise resources; it provides instant online access through a dashboard-like interface.

The interactive level represents the interaction of the developers with their clients and partners. This level propagates the enterprise knowledge to the previous level for strategic analysis and decision-making. An instance of this level is a customer relations management (CRM) system.

The next level represents the resource planning; it consolidates the data from the lower level(s) to form a forecast dynamics of the key production indexes, such as revenues, profits, overheads and expenditures. An example of this level is a resource planning system.

The accounting level contains relatively lower-level subsystems for accounting, warehousing, inventory management and the like.

The supervisory level contains the interfaces between software and hardware components. This level embraces the SCADA systems for field-based devices and sensors, which perform assembly line production and similar plant level operations.

The data level represents databases and data warehouses. This level includes DBMS with data mining plug-ins, middleware, and lower level content management tools.

The hardware level is the lowest; it includes hardware devices and human-machine interfaces. The hardware level aggregates analog data, digitizes and processes them for the upper levels (Zykov, 2015).

HUMAN FACTORS: BUILDING A CRISIS-RESPONSIVE COMMUNICATION

In a crisis, the so-called “human factor errors”, which result from critical uncertainties and anarchic, undisciplined lifecycle management, often dramatically influence the product quality and the project outcomes.

Communication as a “soft” skill and as a process is mission-critical for software development; miscommunications often result in crises. The crisis agility suggests a process framework based on informing science (Cohen, 1999) and Shannon’s communication model (Shannon, & Weaver, 1949). The basic framework includes a transmitting side (i.e. the client), a receiving side (i.e. the developer), and the environment (i.e. the set of software systems at their sites). The model for the basic process framework is an oscillating circuit with a capacitor and an inductive coupling, which uses a feedback loop to oscillate.

A crisis requires a more complex model. First, the communicating sides are informing systems by themselves (Gill, & Bhattacharjee, 2007). Second, the informing circuit requires a feedback controller to model resonant communication. Third, to model bidirectional feedback control the informing circuit requires positive and negative feedback loops.

Typically, the positive feedback increases the amplifier gain, whereas the negative one reduces it. Uncontrolled positive feedback may cause unwanted spontaneous oscillations; this models a situation when the resonance no longer promotes communication. Uncontrolled negative feedback decreases the gain and models the situation when the output value is too low for communication to happen. The enhanced informing circuit provides controlled resonance, which models reliable communication in the oscillating environment with crisis uncertainties. For controlled resonance, the model requires a dedicated couple of controlled positive and negative feedback loops for each of the communicating sides (Zykov, 2015).

To maintain controlled oscillation, the model requires positive and negative feedback compensators, which turn on when the signal input or output value is out of the preset range. These compensators assist in avoiding spontaneous resonance, which models crisis-related communication problems. The circuit requires thorough compensator testing to ensure that both kinds of feedback are within prescribed ranges. The posi-

tive feedback assists in a resonant communication; it also helps to compensate for the noise, which is a likely source of a miscommunication and, consequently, a crisis. For controlled communication, the enhanced circuit uses a calibrated bidirectional feedback circuit, which keeps the informing signal within the prescribed operating range (Zykov, 2015).

CRISIS-RESPONSIVE KNOWLEDGE TRANSFER PRACTICES

In a crisis, it appears that a set of key practices essentially influences knowledge transfer between the client and the developer. Some of these knowledge transfer practices are also known as the “seven principles”; they assist the “informed” communications between the client and the developer (Ambrose, Bridges, DiPietro, Lovett, & Norman, 2010) and significantly enhance the informing science framework (Cohen, 1999).

To promote knowledge transfer, the following practices are mission-critical: prior knowledge, knowledge organization, mastery, feedback, course climate and motivation. Concerning prior knowledge, the two communicating sides usually relate what they learn to what they have known previously; they interpret new knowledge in terms of their prior knowledge (National Research Council, 2000). The client’s side tends to relate prior knowledge to that which is new; however, in crisis this prior knowledge often is inappropriate or incomplete (Resnick, 1983; Alvermann, Smith, & Readence, 1985). Analogical reasoning tends to bridge the gap between the two kinds of knowledge; it helps focusing on deeper concept relationships rather than misleading surface similarities (Gentner, Loewenstein, & Thompson, 2003; Zykov, 2015). The clients with clearer goals often use better strategies for crisis-responsive communication (Barron, & Harackiewicz, 2001).

Mastery as a crucial human-related factor includes competence and consciousness (Sprague, & Stuart, 2000). In crisis software management,

junior developers and architects often underestimate application of their skills to multiple contexts; adaptive mentoring tends to build up their mastery (Cognition and Technology Group at Vanderbilt, 1994; Zykov, 2015).

The synergy of feedback and practice yields to well-balanced theoretical knowledge and a practical skillset. For resonant knowledge transfer, practice and feedback should focus on the same project objectives (Ambrose, Bridges, DiPietro, Lovett, & Norman, 2010). In crisis, the feedback should be prompt and frequent; even a short feedback, if immediate, frequent and individually mentored, promotes knowledge transfer (Hattie, & Timperley, 2007; Anderson, Corbett, Koedinger, & Pelletier, 1995).

Personal and team process improvement requires an efficient metacognitive cycle with iterative evaluation and adjustment (Pascarella, & Terenzini, 2005). In crisis, metacognitive skills are mission-critical; recommended software engineering techniques include self-reflection, team-based concept mapping and brainstorming (Novak, 1998; Zimmerman, 2001).

Other crisis-responsive practices are clear-cut ground rules, transparent policies, cognitive load minimization goal-directed feedback, and an open and friendly environment (Ambrose, Bridges, DiPietro, Lovett, & Norman, 2010; Gill, & Bhat-tacherjee, 2007; Zykov, 2015).

FUTURE RESEARCH DIRECTIONS

The authors found that the crisis in software development was driven by technological and human-related factors. The technological factors were largely driven by software system technical complexity; they can be managed by divide-and-conquer strategy. In a crisis, however, human factors often become mission-critical; this group of factors relates to software management complexity. To manage these human-related factors, agile development methods are usually efficient; these methods are typically team focused, flexible and

adaptive. The authors identified such agile methods and practices; however, their exact influence on particular human factors are intricate, hard to detect and to describe in detail. These intricate relationships between agile methodologies and the mission-critical human-related factors are a prospective research area. The authors also identified and prioritized a set of principles for successful information transfer between software product clients and developers. However, a number of dependencies between these principles is still a matter of future research.

CONCLUSION

The authors analyzed the nature and root causes of the software development crisis which started in the 1960s and, as some researchers argue, is still present. The crisis resulted from a number of factors, which included technological ones and human-related ones. The first group of factors originates from technical complexity, while the second one results from management complexity of the software products.

Software production involves multiple sides with clearly different expectations and goals. In a crisis, efficient managing of these human-related factors becomes mission-critical. Communicational misconceptions between the sides often result in a software product which may not meet the clients' expectations. To manage this software delivery crisis, the authors recommend an optimization strategy for the technical and human factors by means of software engineering models, methods, techniques, practices and tools. This strategy includes risk management models, agile methodologies, system-level architectural patterns, an informing process framework, and a set of knowledge transfer principles. This strategy, if applied systemically, should essentially help to optimize the software development process and to manage the crises of software production.

KEY TERMS AND DEFINITIONS

Agile: A software development methodology; an alternative to traditional project management where emphasis is placed on empowering people to collaborate and make team decisions in addition to continuous planning, continuous testing and continuous integration.

Agility: Ability to adapt to uncertainties and changes of environment.

CMM (Capability Maturity Model): A methodology used to develop and refine an organization's software development process.

CMM(I) (Capability Maturity Model Integration): A framework of best practices in managing, measuring and monitoring software development processes.

COCOMO (Constructive COst MOdel): An algorithmic method for evaluating and estimating the cost of software development.

COCOMO II (CONstructive COst Model II): A method for estimating the cost, effort, and schedule when planning a new software development activity.

Crisis: Misbalanced production and realization of a surplus value, the root cause of which is separation between the producers and the means of production.

CRM (Customer Relationship Management): A set of practices, strategies and technologies that companies use to manage and analyse

customer interactions and data throughout the customer lifecycle, with the goal of improving business relationships with customers.

Enterprise Agility Matrix: Matrix, the columns of which correspond to processes, data and systems, and the rows of which contain enterprise system levels. Used to detect and predict local crises of software production.

Human-Related Factor: A factor originating from human nature, which influences requirements elicitation, and, consequently, software development.

MSF (Microsoft Solution Framework): A software development methodology; a set of principles, models, disciplines, concepts, and guidelines for delivering information technology solutions from Microsoft.

OOAD (Object-Oriented Analysis and Design): An approach in the system analysis and design through the application of the object-oriented paradigm and concepts including visual modelling.

Oscillator Circuit: An electric circuit, which consists of capacitor and inductive coupling. Uses feedback for oscillation.

Price-S: A composite modelling system for estimating software cost.

Quality Attribute: A systemic property of a software product, which critically influences its quality.

RUP (Rational Unified Process): A software development methodology; a software development methodology from Rational. RUP organizes the development of software into four phases, each consisting of one or more executable iterations of the software at that stage of development: inception, elaboration, construction, transition.

SADT (Structured Analysis and Design Technique): A software engineering methodology for describing systems as a hierarchy of functions.

Sage: A model for estimating software development; includes project management and personnel characteristics.

SCADA (Supervisory Control and Data Acquisition): A category of software application for process control; gathers data in real time from remote locations in order to control equipment and conditions.

Scrum: An iterative and incremental agile software development methodology for managing product development.

Seer: A model for estimating IT project and service costs.

Software Design Pattern: A general reusable solution to a commonly occurring problem within a given context.

Software Engineering: A set of tasks, methods, tools and technologies used to design and implement complex, replicable and high-quality software systems, which include a database.

Third-Generation Programming Language: A high-level programming language such as FORTRAN, COBOL, BASIC, Pascal and C.

XP (eXtreme Programming): A software development methodology which is intended to improve software quality and responsiveness to changing customer requirements; a pragmatic approach that emphasizes business results and takes an incremental approach to building the product through continuous testing and revision.

Information Science and Technology in Crisis Response and Management

Randy Basham

University of Texas at Arlington, USA

INTRODUCTION

Emergent technological innovations in robotics and miniaturization of robotics, drone technologies, acoustical sensors, and others are revolutionizing the effectiveness of crisis response and management efforts, on smaller local events, and in combination, may be applied to larger disaster events such as major community or regional crises. These have also been supported by advances in tracking, communications, information dissemination, identity verification, and location technologies developed over that past decade since Hurricanes Katrina and Rita devastated the central populated region of the United States and Central North America. The combination of these technologies show promise of rapid intervention and rescue, within the most devastated areas affected by major environmental and man-made disasters as they are scaled up to address larger population supports. Location and allocation of resources to the individuals, families, and populations of need may occur nearly unimpeded by obstacles, debris, contaminants and human first responder high risk environments. As these technologies are systematized and develop some level of autonomy in technological problem solving, they are likely to improve overall survivability of populations at risk in the most disaster fragile of environments.

BACKGROUND

Early efforts to link crisis management and information technology were concerned with the protection and maintenance of data within private

business organizations. Businesses' have become dependent on technology to perform work, distribute products and improve productivity and efficiency. Loss of technology functions and critical information could cause irrevocable damage to a business. Therefore crisis management in the business sense has meant anticipatory planning for disruptions and protecting data and process critical for business success. The use of experts within a domain of business services coupled with domain decision makers and gathered into crises management teams; has been highly useful in considering critical scenarios of information or other critical processes disruption or loss. Constructing anticipatory action plans has proven to be a key part of adequate preparation for response, though these must be updated as situational contexts and key personnel change (Esbensen & Krisciunas, 2008).

Approximately a decade ago, in North America the major disasters of Hurricanes Katrina and Rita (Hurricanes: Science and Society, 2015) and there combined effects on a region of the south central United States were heavily televised, in part because of the urban location of the disaster in a modern and well known city. Major humanitarian service providers such as FEMA and the American Red Cross began to grapple with the scale of information needed and service provision possible for such large scale disasters and began seeking community and academic partnerships with corporate information technology providers, the defense industry, uniformed military service providers (especially those engaged in search and rescue efforts) and governmental agencies to improve crises response and management, for disasters of scale (Hurricane Katrina Disaster Relief, 2015).

DOI: 10.4018/978-1-5225-2255-3.ch121

Since this time several additional cataclysms have increased awareness for the need to look at international and global response systems involving information technology, relative to preparedness, systemization, planning, pre-positioning of resources and equipment, logistics and distribution capacity in the management of crisis and disaster management. Public attention has been galvanized by devastating natural disasters such as; earthquakes in Pakistan in 2005 and in Sichuan China in 2008 and again in Haiti in 2010, the Tohoku earthquake and tsunami striking Japan in 2011, Cyclone Nargis that struck Myanmar in 2008 and by recent recollections of earlier but recent large scale disasters prior to the North American hurricanes of 2005 such as; the Sumatra tsunami of 2004, and the Iran earthquake of 2003, and several earlier to these and many others since (Lists of Disasters, 2015).

CRISIS RESPONSE AND MANAGEMENT: TECHNOLOGY CONSIDERATIONS

Crises and disasters are sudden and unforeseen. Each is serious, disruptive, overwhelming and often exceeds capacity to restore order and normalcy in any expected time frame. However, crisis or disaster events may occur with some frequency and predictability, and standardized responses may be thoughtfully and consistently applied. Others may be anticipated to occur occasionally but irregularly, and require a level of creativity and innovation over a short period in response. There are of course, improbable and unexpected crises and disasters which occur infrequently, but of which there are no precedents or examples to follow, and for which we have little or no prior experience. These are often widespread and devastating occurrences, requiring longer term determination and resolve to manage and to overcome or restore some level of normalization. Technology and information based systems may be designed to address each, as these relate to specific probabilities for their occurrence,

and with attention to scalability of responses as needed for each type of crisis or disaster.

SWOT (Strengths, Weaknesses, Opportunities, and Threats) Analysis for Institutions

Though there are a number of possible and foreseeable crises that may affect any organization, information science technology is emerging as a critical crisis response consideration. Economic downturns, loss of funding, loss of physical and human assets, and employee litigation (Crisis Management, 2016) may all be tied to the consistency sustainability and privacy issues associated with information technology management protocols and continuity. A strategic planning method that may be quickly used by employees not fully familiar with an organization is to develop a simple SWOT plan of key and critical inquiries relative to information technology management or other strategic plan, crisis response initiative of the organization. Some possible lines of inquiry and planning for information technology management are given in Table 1 below, these should be strategically prioritized and determined both internally and externally:

Information Science Technology: Institutional Crisis Response and Management

Crisis response and management as related to institutions, or business, information science and technology requires crisis management teams are often designated in advance of a crises and focus crisis and recovery plans on avoiding a crisis, preparing and planning for crises, identifying threats and critical systems for protection, training key personnel for crisis events and recovery, communicating plans to organizational members, and reviewing and updating plans and disseminating crisis response guidelines. Phases of institutional Crises Stages (Fink, 1986) involving information technology have been identified as:

- **Prodromal Stage:** The first time those potential crisis symptoms occur. Early warnings may be missed, or may not occur creating unexpected crisis and causing decision makers to revert to a damage control process rather than preventing or limiting damage (Fink, 1986).
- **Acute Stage:** There is no preventative recovery, or turning back. The crisis begins and the eruption is noticeable. The crisis ends when the damage or disruption becomes unnoticeable (Fink, 1986).
- **Chronic Stage:** The recovery phase includes investigations, audits, explanations, self-analysis, self-doubt and healing. This phase is often used to analyze what went wrong and how to improve response in future (Fink, 1986).
- **Resolution Stage:** The crisis is resolved by managing the three prior phases of crisis. Alerts or prodromes are taken seriously in anticipation of avoiding or reducing the effect of any upcoming potential or foreseeable crises (Fink, 1986).

Most institutions with crisis management experience relative to information technology develop contingencies to suppress the destructive potency of a crises or critical event.

Key Theories Underlying Crisis Response and Disaster Response

At the institutional level crises are perceived as situational threats that may affect institutional reputation which may be moderated by application of communication theory, to minimize reputational harm (Coombs, 2007). Though larger scale disruptions external to the institution that may require disaster response are influenced by chaos theory and the perceived need to restore normalcy (Kiel, 1995). Similarities in each of these approaches to retain stability, or restore stability during periods of extreme stress to the institution or greater environment may be identified in

classic crisis intervention theory as conceived by Aguilera and Messick as early as 1970. Crisis Intervention Theory maintains, that pre-existing equilibrium may be disrupted and result in disequilibrium among human organisms at the onset of extreme or prolonged stress. There is a pressing need to restore equilibrium. If there are sufficient balancing factors present, then no crisis occurs, or is sustained. Though, if sufficient balancing factors are absent, then a crisis will occur, or be sustained, though a lesser or less adequate level of equilibrium may still be possible (Aguilera, Messick, & Farrell, 1970).

Developing Crisis and Disaster Prevention and Response Infrastructure

A number of organizations and corporations are actively engaged in developing the technological architecture for preventing both institutional and non-institutional crises and disasters that occur with some frequency, and require standardized responses. These are preventable crises and probable disasters, or those of which a known infrastructure may be developed to rapidly and efficiently respond, so as to reduce loss of control. The costs of development are justifiable, and incidence rate may be statistically tracked with some accuracy for prediction of occurrence. These include those events that may be anticipated, and allow sufficient time to prepare for. Preparation is based upon what is known and what may be known, of which, there is an ability to take preventative action, and that there is an ability to plan to act to maintain or regain control where possible. Recent information technology advances related to crisis or disaster response capacity may be seen in Table 2 below:

Individual Hazards Reduction: Disaster Response and Management

Disaster response and emergency management may be related to single institutions as causal (i.e. Bhopal India, Chemical Spill in the 1980's),

though the effects are often experienced community wide or regionally, whether manmade or natural. A single natural event may also be causal, but cause unexpected community and regional effects across institutions and technologies. These disrupt daily living and livelihoods, and cause loss of life, community structures, and normalcy, are widespread, and last for longer periods. Emergency Management Phases (U.S., FEMA, 2015) involving local or regional recovery, but those focuses upon individual or small group responses have been identified as:

- **Mitigation Phase:** Preventing future emergencies or minimizing their effects. Includes any activities that prevent an emergency, reduce the chance of an emergency happening, or reduce the damaging effects of unavoidable emergencies. Buying flood and fire insurance... (U.S., FEMA, 2015).
- **Preparedness Phase:** Preparing to handle an emergency. Includes plans or preparations made to save lives and to help response and rescue operations. Evacuation plans and stocking food and water are both examples of preparedness. Preparedness activities take place before an emergency occurs (U.S., FEMA, 2015).
- **Response Phase:** Responding safely to an emergency. Includes actions taken to save lives and prevent further property damage in an emergency situation. Response is putting preparedness plans into action. Seeking shelter from a tornado or turning off gas valves in an earthquake... (U.S., FEMA, 2015).
- **Recovery Phase:** Recovering from an emergency. Includes actions taken to return to a normal or an even safer situation following an emergency. Recovery includes getting financial assistance to help pay for the repairs. Recovery activities take place after an emergency (U.S., FEMA, 2015).

Most individuals, families, small groups, or some communities with disaster or crisis management training or experience develop contingencies to suppress the destructive effects of an emergency or disaster, including preparing for disruptions in information and media access, and energy, transportation, and communications disruptions. However, larger scale disasters may overwhelm these individual efforts.

Fragile and At Risk Systems and Environments

Within fragile, or at risk, business, manufacturing, or service systems, or within geographically defined areas such as a neighborhood, community, nation, or region, infrastructure to resist various forms of crisis or disaster effects, either natural or manmade is often inadequate for the risk profile of the institution or area (ReliefWeb International, 2015). Technology may be defined differentially, based upon the specific crisis prevention and response infrastructure needed for recovery. For example, regional risks may include inadequate roads, transportation, water supplies, food, or agricultural supports, weather reports, available media, energy access, shelter or insulation from the elements, access to money, or commercial goods needed for survival, medication, medical care, hygiene supplies, information, and communication, though this listing is not exhaustive. Each facility, institution, community, or geographic area or environment has a uniquely definable fragility, or risk profile. Planning, pre-positioning of equipment, services, or supplies and the systematic addressing of infrastructure limitations may attenuate the devastating effects of a crisis or disaster. Information technology is an essential part of and critical requirement in the evaluation of fragility and the provision of effective decision supports to responders and disaster response organizations. Recent device technology advances related to crisis or disaster response capacity may be seen in Table 3, below:

Humanitarian Action in Crises and Disaster Response

Whether the crisis is of smaller scale or more broadly distributed and classified as a disaster, local people such as: organizational volunteers, employees, or available citizens, with or without adequate supportive equipment or training, are most likely first responders. Approximately 90% of lives saved in a life threatening disaster are saved by local people (Calhoun, 2015). These first responders are themselves vulnerable to the same threats and losses as those they are attempting to rescue. These responders often have limited access to adequate and timely information, communication capacity, and needed health care services and medical expertise, or medications and medical supplies. In smaller crises, lack of information, communication and available but needed equipment and expertise are common. Smaller crises however, if unattended may increase risks for the development of full blown disasters if unresolved, within a risk reduction time frame (Author, 2006).

Post Crisis or Disaster: Resilience Engineering

The quote attributed to George Santayana, *Those who cannot remember the past are condemned to repeat It* (Internet Encyclopedia of Philosophy, 2015) with a variant frequently used by Sir Winston Churchill *Those who fail to learn from history are doomed to repeat It* (National Churchill Museum Blog, 2015) provide in their historical contexts sufficient example and justification to improve conditions following crises and disasters that could not be reasonably predicted to assure that they are less likely in the future.

Engineers and decision makers are increasing reliance on the principles and practices of resilience engineering for strengthening infrastructures and to reduce fragility and risk, due to potential damages from crisis or disaster.

Resilience engineering (Resilience Engineering Association, 2015) is an emerging and non-conventional approach to risk management, especially in engineering that examines methods to improve the ability at all levels of organizations to create processes that are robust yet flexible, to monitor and revise risk models, and to use resources proactively in the face of disruptions or ongoing production and economic pressures. Relative to information science and technology, the concept of information technology, communication technology, or computing technology failures, by robust design, are not due to the breakdown or malfunctioning of normal system functions, but are more likely to represent the limitations of human operators to anticipate adaptations necessary to changing conditions in the real world.

Issues, Controversies, Problems

Improving the saving of life and the limitation of longer term adverse effects during disaster is in part due to recent advances in strategic hardware devices such as remote telemetry, surveillance, multipurpose vehicles, including amphibious vehicles, and aerial unmanned surveillance and package delivery vehicles (drones). The capacity to gather situational awareness information remotely through acoustic sensors and bio monitors, ground and object penetrating scanning devices have greatly improved critical information gathering for crisis and disaster management. Additionally, mechanical or robotic search devices, and the interconnectivity of these between multiple information systems and operators, either human or computing, are also reducing barriers to rescue and recovery efforts.

SOLUTIONS AND RECOMMENDATIONS

Often technologies that have intelligence gathering capacity, logistical capacity, risk evaluation

capacity and autonomous decision making ability are used for defensive and military purposes. However, these same technologies show great promise of being able to ameliorate the damage and destruction created by both natural and manmade disasters, as well as crisis response at the institutional level. Deploying these technologies and a wide scale and imaginative engineering focused upon improving the hardiness or resilience of civil, municipal, transportation, communication, information science and related structures will also mitigate the effects of crisis and disasters and improve overall response, and recovery.

FUTURE RESEARCH DIRECTIONS

Improved information science driven mapping and location technologies, including, for persons at risk or endangered, in a crises or disaster, automated deployment of assets, at a threshold level of early warning, improved logistics in planning and prepositioning and distribution of needed resources, are all critically needed areas for additional research. Rapidly self-correcting decision making software or applications for critical information systems restoration (financial, energy, information, etc.) would reduce legacy losses of vital knowledge needed to continue organizational, institutional, community or regional functions.

Advanced light weight composite material with protective and insulating properties that may be used as wearable information science interface platforms as clothing and with embedded bio sensors and others focused upon external environmental or risk conditions need further additional inquiry and would likely enhance the effectiveness of response personnel. Miniaturization, stable energy source, and autonomous functioning and sensing capacities for robots, drones and others would rapidly reduce risks in locating those in need and reducing risks. Networked visual (camera systems) through damages areas either urban or rural would also contribute to crises response.

CONCLUSION

Crisis response and management have improved steadily with access to improved situational awareness and information distribution. Satellite systems have improved weather prediction, and advanced warning alerts for some naturally occurring disasters. Emerging sensor technologies may improve earthquake and tidal wave or tsunami predication as previously difficult to predict natural events. Global positioning satellite systems have improved mapping and location technologies to enhance disaster location and improve logistical responses. Satellites have also improved knowledge of slowing developing disasters such as droughts, or water level and availability changes. These have assisted in providing additional supports to affected regions over time. The transmission of vital information over the internet and in combination with satellite technology, media broadcasting globally, and the advent of cloud storage or off site storage of critical information and redundant information archives have limited data and information loss and improved consistency and availability of access to both decision makers and affected populations during an emergency. Indeed the emphases on crisis response or disaster response and management knowledge for corporations, other institutions, helping organizations, the military services and governments have led to widespread and more focused levels of preparation and likelihood of limiting damages during a crisis, information based, or physical.

KEY TERMS AND DEFINITIONS

Crisis Management: The application of strategies designed to help an organization, or community, deal with a sudden and significant negative event.

Crisis Response: The methods used to offer short term immediate help to individuals who have experienced a crisis, disaster or catastrophic event.

Device Technology- Crisis/Disaster Response: Mobile devices and technology enhanced mechanical devices with computing and problem solving capabilities, networked communication capacity, remote sensing and transport abilities to provide, alerts, response assistance and rescue assistance.

Fragility – Fragile, At Risk, Environments: Easily broken, shattered, or damaged; delicate; brittle; frail: a fragile ceramic container; a very fragile alliance, also applies to communities, regions or nations with limited capacity or infrastructure to recover from calamity.

Information Science: The study of processes for storing, organizing, retrieving or recovering information, especially scientific or technical information.

Information Technology- Crisis/Disaster Response: The study or use of systems (especially computers and telecommunications) for storing,

retrieving, and sending information; routinely or in special event circumstances, or condition.

Manmade Disaster: Anthropogenic hazards or human-made hazards can result in the form of a human-made disaster. In this case, anthropogenic means threats having an element of human intent, negligence, or error; or involving a failure of a human-made system. This is as opposed to natural hazards that cause natural disasters.

Natural Disaster: A natural event such as a flood, earthquake, or hurricane that causes great damage or loss of life.

APPENDIX 1

Table 1. SWOT Analysis for IT Management and Crisis Response (Situation being analyzed: Information Technology Loss or Disruption)

Strengths What is the company doing well, relative to information technology management? What information technology resources does the company provide that are important to continuity, sustainability and crisis response? Is the company making best use of available information technology?	Weaknesses What resources or services could the company improve, relative to information technology management? What areas does the organizational competition have a technological edge relative to information technology management? What adverse information technology should the organization actually avoid?
Opportunities How will information technology change? What are the interesting trends in technology that could be exploited? What needs in the information technology market are not being addressed by others?	Threats What is the competition doing well, relative to information technology? What information security threats should the business be most concerned about? What new innovations are others bringing, that would affect information technology management?

APPENDIX 2

C

Table 2. Information science and technology: crisis or disaster information technology advance

Information Technology Advance	Crisis/ Disaster Response Capacity
Satellite and transmission technology (including radio, video, ham radio, etc.)	Satellite conveyed information has become the primary conveyance system for information, communication, and geographic location data. Though satellites were originally designed to serve military and entertainment roles, over time they have become a tool for humanitarian and educational transfer of knowledge.
Computing capacity	Communications, information dissemination, data archiving, automation of routine tasks such as sending or updating alerts, automated calling or text messages
Data archiving capacity	Cloud based archiving of data, large hard drives, large servers, portable memory devices, data backup services and devices, etc.
Graphical user interface	Windows and Macintosh operating systems and proprietary corporate and other derivations, including a mouse or similar device, to select and display information rapidly
Global positioning data, global imaging data	GPS location, Google Earth and similar photo mapping applications (Google Earth, 2015).
Environmental data server, geographic information systems	Mapping, weather, and available distinguishing features, services available, terrain and available transportation routes (Google Crisis Response, 2015).
Mobile technology, personal and configurable, connectivity to information systems	Cellular phones, paging systems, text message, and email or automating phone message delivery upon detection of any predetermined activating event; capacity to archive directories of contacts and key services locally; capacity to access the internet to search for information or help; capacity to download customized application on rendering first aid, locating transportation, etc.
Crisis informatics	Continuous situational updating and risk parameter information either queries or automatically updated and displayed, or communicated
Crowdsourcing of data.	Matching or linking applications, that match available supplies to need within an area, match volunteers to disaster area, match perspective labor with available work, etc. (Google Person Finder, 2015).
Identity verification	Online financial and membership application that confirm, or authenticate identity
Tracking technologies	RFID chips, embedded in credit cards, or ID cards and GPS applications located in mobile phones, vehicles, or with assigned personnel or emergency broadcasting device
Post disaster reunification of children with families	(The National Center of Missing and Exploited Children; Unaccompanied Minors Register, 2015), (USA)
Simulators	(Search and Rescue Optimal Planning System, 2015). US Coast Guard (SAROPS) is made up of the Graphical User Interface (GUI), the Environmental Data Server (EDS) and the Simulator (SIM) which can predict: 1. probability of containment, 2. probability of detection, and 3. probability of success
Social networking	Provide an online location for family members, friends or contacts to check in and locate each other, update news, or share alerts: Facebook, Twitter, and similar networks

APPENDIX 3

Table 3. Information science and technology: interdependent crisis or disaster technology devices

Device Technology Advance	Crisis/ Disaster Response Capacity
Remote and portable sensors and transmitters; acoustic, biological, chemical, infrared, microwave, motion, thermal, radiation, visual, and others	Depending upon energy supply, sensors may be connected to computing and tele communications networks to provide continuous or situational monitoring and updating broadcasted to any configured receiver at distance.
Smart clothing, insulating and protective fabrics, sensor and transmission devices, exoskeletons, etc.	Clothing may be configured as shelter, protective device against injury, as a technology platform for sensing and communication; with designs currently available; exoskeletons permit the wearer to reduce limitations of some disabilities and increase body strength or endurance
Biological and health sensors; on person, in location	Exposure to specific contaminants, Wi-Fi enabled health monitoring software (cardio, pulse, EKG, EEG, kinesiology, etc.).
Linked camera systems, municipal and other	Traffic cams, sport event cams, accessible, security and weather cams, etc.
Water purification and transport devices and distribution	Solar powered portable mobile water purification systems, mobile dispatch software for water transport supplies, logistics tracking and volume
Food preservation and long term storage devices and distribution	Pulsed electric and magnetic field treatment to inactivate bacteria and limit quality loss in transport and storage, packaging and oxygen removal, mobile dispatch software for food transport supplies, logistics tracking and volume
Energy storage and production and distribution	Long term marine batteries that hold charge up to 10 years, mobile fuel powered generators, portable solar panel, mobile power plants, etc.
Portable and temporary shelter	(ShelterBox, 2015), an international disaster relief agency along with Rotary International, provides inexpensive relief shelters. The organization has tracking systems to monitor weather systems, the likely scale of hurricanes and cyclones and earthquake alert system. Other temporary shelter companies provide similar.
Advanced extraction, evacuation and hazard clearing tools	Devices or mechanical appendages often networked and monitored which are attached to multipurpose transportation devices and have specialized functions. Example; chain saws to clear hazards or obstacles, mobile battering ram, bomb detection, etc.
Transportations systems (unmanned) and human responder interface, or independent function	(Lynxx, 2015) Multipurpose vehicles, amphibious vehicles, drone technologies, etc.
Robotics and human responder interface, search, burrowing, medical, etc.	Larger automated and frequently mobile mechanical devices with some computing and communication capacity and other specialized functions or capacities such as: traversing difficult and hazardous terrain and gathering risk and other information, transporting supplies, digging or repetitive manualized labor tasks, and performing human supervised medical procedures at a distance
Miniaturization of robotics, and human responder interface, or independent function (disaster response micro robots)	Remote sensing devices, including miniature cameras attached to miniaturized robots to perform search or information gathering functions in high risk environments

Curriculum Development and Instructional Design

Addressing Digital Competencies, Curriculum Development, and Instructional Design in Science Teacher Education

Isha DeCoito

Western University, Canada

INTRODUCTION

New realities of the 21st century demand individuals with different competencies than those considered appropriate for success in the past. Consequently, education must change. Milton (2015) maintains that surface changes in education will not equip students for the 21st century and that change is needed at the core of educational practice. A shift must occur from the traditional view of educational practice to a transformative view. Moreover this shift must aim to incorporate technologies in schooling in a manner that digress from disciplinary experts' determinations of what and how students should learn – a classic perspective which has resulted in challenges for educators as they continue to search for strategies to effectively address the development of skills reminiscent of the preferred learning styles of today's students.

With each passing year, technology becomes a more predominant part of educational culture (Bolstad & Gilbert, 2006; Cox, 2008). Simply introducing technological tools and infrastructure into schools will not trigger beneficial and meaningful educational change. Moreover, technology cannot be effective in the classroom without teachers who are knowledgeable about both the technology itself and its implementation to meet educational goals, that is, teachers who are technologically literate. Thus, it can be said that, while technology use in the classroom is increasing, improving learning through the application of these literacies should remain the

goal. Changes are inevitable if technology is to make a difference in curriculum design and address the needs of 21st century learners. The impact of technology and the changing face of curriculum, as well as the accompanying changes in the roles of teachers can no longer be ignored; roles must be reconceived in order to engage learners in many decisions about their learning (Bennett, 2002; Bolstad, Gilbert, McDowall, Bull, Boyd, & Hipkins, 2012). Achieving changes associated with the integration of technology in the overall learning environment will require efficient teacher training in teacher education programs (Brush & Bannon, 1998). This begs the question: What kinds of modeling and scaffolding should educators or designers provide to help learners engage in this process?

Teacher professional development (PD) is absolutely essential if technology is to be used effectively; PD should entail initial preparation/training – pre-service, in-service, and ongoing pedagogical and technical support for teachers as they address their daily challenges and responsibilities. Training and on-going inquiry-based approaches imply that support should go beyond teaching skills in technology use and focus on the effective pedagogical use of the technology to support teaching and learning goals (DeCoito & Richardson, 2016).

In this article the author reports on a mixed-methods study with a focus on science teacher education. Specifically, the study addresses the development of secondary science teacher candidates' (TCs') digital competencies as they

explored the integration of digital literacies in a science methods course, and its potential to enhance teaching and learning in science, including curriculum and instructional design. The author maintains that in order to develop the necessary skills and application practices of technology integration, and enhance technological literacy, TCs must be presented with appropriate experiences in teacher induction programs.

BACKGROUND

Teaching and Learning in the 21st Century

The preparation of young people for lifelong learning in a 21st century knowledge-based information society has become an increasingly important objective of educational systems worldwide (Dagiené, 2011). Multi-literate, creative and innovative individuals are seen as “drivers of the 21st century and the prerequisites to economic success, social progress and personal empowerment” (Canadians for 21st Century Learning and Innovation, 2012). A primary challenge for education is to transform student’s learning processes to engage student interest in gaining 21st century skills and knowledge. Lemke (2004) reported a link between 21st century skills and academic achievement, making the case for incorporating teaching activities, including digital technologies that nurture these skills (see further elaborations, National Research Council, 2011). Despite the fact that these skills have been around for a very long time, currently the challenge is, according to Bolstad et al. (2012), “how to achieve a shift that creates a more coherent educational ecology that can support what is known about good learning *and* that can accommodate new knowledge about learning and, importantly, new *purposes* for learning in a changing world”. As such, there is a need for students to experience opportunities that will result in enhancing 21st century learning skills.

The acquisition of 21st century skills in teaching and learning will require a shift in what we teach, how we teach it, the tools we use and how we educate, train, nurture, and retain our teachers. It is undeniable that we cannot change how our students learn unless our teachers are equipped to teach in new ways (Murnane & Levy, 2004). Thus, the scope and components of the research underlying this article were informed by the conceptual framework of a constructivist model of learning applied to teacher education – acknowledging that for TCs to develop their ability to teach, they must be provided opportunities to actively construct their understandings of pedagogical content knowledge (Chai, Koh, & Tsai, 2010; Graham, 2011) and integrate new understandings with prior knowledge (Hollingsworth, 1989; Shulman, 1986) under a technological, pedagogical, content knowledge (TPACK) framework (Mishra & Kohler, 2006). The constructivist view of education suggests that the theory of individual learning is flawed and furthermore, is not conducive to multi-literacy pedagogy in multimodal environments. The constructivist view is that students learn best, not by assimilating what they are told, but rather through a knowledge-construction process (Bereiter, 2002). In order for individuals to learn how to construct knowledge, it is necessary that the process be modeled and supported in the surrounding community; that is, a learning community. In a learning community the goal is advancing the collective knowledge while supporting the growth of individual knowledge (Scardamalia & Bereiter, 1994). The defining quality of a learning community is that there is a culture of learning, in which everyone is involved in a collective effort of understanding. This was in fact nourished, supported, and modeled throughout the science methods course as teachers engaged with digital literacies on various levels.

Digital Literacies

Education today is faced with the challenge of adapting to an environment where literacies are

becoming ever more important –how knowledge is represented, as well as the mode and media chosen, is a crucial aspect of knowledge construction, making the form of representation integral to meaning and learning more generally (Cope & Kalantzis, 2000; Martin & Grudziecki, 2006). It follows, then, that to better understand learning and teaching in the multimodal environment of the contemporary classroom, it is essential to explore the ways in which representations in all modes feature in the classroom (Jewitt, 2008).

The term ‘digital literacy’ is contested, and understood in different ways by different people and is often referred to as “digital competency”, meaning a set of knowledge elements, abilities, dispositions, and conducts that enable individuals to know how ICTs work, what they are for, and how they can be used to attain specific objectives (Castells, 2009; Grant, 2010). Digital literacy has also been defined as an umbrella framework for a number of complex and integrated sub-disciplines comprised of skill, knowledge, ethics and creative outputs in the digital network environment (Calvani, Cartelli, Fini, & Ranieri, 2008). The shift in our society’s growing reliance on technology mandates that education emphasize technological/digital literacy including: digital competence (skills, concepts, approaches, attitudes), digital usage (professional/discipline application), and digital transformation (innovation/creativity) (Belshaw, 2011). According to Spires et al. (2012), when considering digital literacy one can organize the related cognitive and social processes into three categories: i) locating and consuming digital content; ii) creating digital content; and iii) communicating digital content.

ICT are reshaping the ways in which students learn and prefer to learn, including fluency in multiple media and simulation-based virtual settings and co-designing learning experiences that are personalized to individual needs and preferences (Annetta, 2008). While educators and others have listed and described 21st century skills, teachers continue to search for strategies to effectively address the development of these

skills in the preferred learning styles of today’s students (Bolstad et al., 2012; Greenhow, Robelia & Hughes, 2009). Emerging learning styles signal that teachers adapt their teaching styles, and according to Ng (2010), the new styles should reflect multi-literacies pedagogy which focuses on multimodal ways of conveying understanding. Improving digital literacy underpins not only a nation’s capacity to provide individuals and groups with equity of access to social opportunity; it is a necessity for participation in the digital economy (DeCoito & Richardson, 2016).

Digital Competencies and Science Education

Digital literacy is important for science learning as it i) assists students to learn more effectively with the range of ICT-enabled affordances that have the capacity to motivate and enable better understanding of science concepts, and ii) lessens the working memory’s cognitive load, while learning science that is ICT-based (Ng, 2011). The affordances offered by ICT benefit science learning and potential benefits of integrating digital literacy in science education have been documented, including increasing student motivation (Osborne & Collins, 2000), expanding the pedagogical resources available to science teachers (Al-Alwani, 2005), promoting cognitive development, and highlighting relevance via relating science to students’ real-life experiences (Webb, 2005). For example, DeCoito (2014) explored how digital scientific timelines can be used to teach about the nature of science, and more recently, the potential of digital games to enhance scientific and technological literacy while teaching STEM concepts (DeCoito & Richardson, 2016).

The challenge for educators is to utilize these aforementioned literacies in ways that facilitate the highest level of learning outcomes. Educators face a number of challenges when deciding to integrate digital literacies in the classroom. Among these are choices about which one(s) to use, how effective the choices are in reinforcing learning, and the

role of these digital literacies in shifting from an instruction paradigm, which is teacher focused, to a learning paradigm, which is student focused (Cox, 2008). Dede (2014) maintains that the goal of using technology should be to empower teachers to make better use of instructional strategies that provide opportunities for self-directed learning, which foster academic engagement, self-efficacy, and tenacity by requiring students to define and pursue specific interests. Furthermore, it should personalize learning, which ensures that students receive instruction and supports that are tailored to their needs and responsive to their interests.

Research studies (Ertmer et al., 2012; Sancar-Tokmak, Sürmeli, & Özgelen, 2014; Sasseville, 2004; Zhang & Martinovic, 2008) revealed that TCs' levels of self-efficacy (Skaalvik & Skaalvik, 2008) and attitudes toward ICT determined whether or not, and how, they used ICT in their classrooms. For example, Ertmer et al. (2012) found that teachers' attitudes towards technology play an important role in their integration efforts. In general, TCs believe that they should become more ICT literate because it may enhance teaching and learning in all classrooms; however, they believe that they do not possess the skills to integrate ICT in their future practices (Gomes, 2005). Dilworth et al. (2012) demonstrated that to use technology effectively, a deep understanding of content and related pedagogical knowledge is essential.

TCs provided various reasons for their attitudes toward the use of ICT in teaching and learning, including lack of adequate teacher training in effective use of ICT in the classroom (Albirini, 2006); fear that time taken for technological training infringes on time for learning content; and concern that an emphasis on technology may distract students and teachers from teaching and learning (Dipetta & Woloshyn, 2009). Despite the affordances offered by ICT, the development of digital literacy may require a focus on technology for initial periods of time. As expertise develops with the technology, learning becomes more learner-centred and over time, the focus shifts to the engagement of learners with science content (Ng, 2011).

THE STUDY

The Course

The science methods course was offered at the senior level and catered to TCs whose speciality was biology, chemistry, or physics. The implementation of technology was promoted widely in this science methods course to expose TCs to multi-literacy pedagogy and develop their technological literacy, as well as engage them in creating digital science content, and promote creativity. The instructor used technology extensively and invited guests to conduct workshops on technology enhanced learning, including biotechnology and the effective use of digital games. The course assignments spanned over two semesters and incorporated the integration of digital literacies (information literacy, computer literacy, media literacy, communication literacy, visual literacy, and technology literacy) on a variety of levels as TCs developed a) digital interactive case studies exploring socioscientific issues; b) scientific timelines using, e.g., Prezi, Movie Maker, Tiki Toki, etc.; c) concept presentations in science (e.g., including digital games, simulations, virtual laboratories, etc.); and d) science resource websites focusing on multimedia interactive activities.

Methodology

A mixed-methods design (Mills, Durepos, & Wiebe, 2010) was utilized to address the development of TCs' digital competencies over a 2-year period. Participants included 39 TCs enrolled in a senior science methods course in a Faculty of Education at a Canadian university. Data sources included questionnaires (views of, experiences with, and attitudes towards technology; and development of course assignments); TCs reflections on the course assignments; audio-taped, semi-structured interviews about TCs' views of the role of digital literacies in science education; and student work. Quantitative data were analyzed using statistical analysis (Microsoft Excel) and de-

scriptive statistics. Qualitative data were analyzed through an interpretational analysis framework executed through the process of thematic coding and constant comparative method (Stake, 2000) to address the goals of the study.

Findings

Teaching and Learning Through Digital Literacies in Science

There was overwhelming agreement amongst the participants for incorporating digital literacies in all levels of science teaching. Reasons cited by TCs included i) engaging students, ii) fostering learner choice and learner control; iii) highlighting relevance between science and technology, iv) personalizing learning, and v) addressing 21st century trends, as illustrated below:

They [students] can do everything they were able to do before, but now they have another door to open and go through ... I taught viruses and the kids were not excited. I had them do Facebook profiles of viruses [like we did in class]... suddenly they were on the Internet and became engaged, interested. I think it's just from the standpoint that they are doing something that isn't usual ... difference is a good thing ... they appreciate the difference in learning and it is very helpful because students can find what they need to learn. This is something the education system is lacking ... by high school, students need to start exacting control over their learning.

So much of this world that we are in today is all about technology, and so, if students aren't learning about technology, they are not really keeping up, so as teachers we have to adapt our teaching techniques to what's going on in the world. If we're going more towards the technology based world, we have to prepare our students to be successful in that world ... students will appreciate it and they will learn different things. If we can teach our students about technology and how to use it,

that would be beneficial for them for whatever they do in their lives.

These findings are supported by Bolstad et al., (2012) and Cox (2008) who maintain that the teacher's role must be reconceived when implementing digital literacies in order to engage learners, their interests, experiences, and knowledge in many decisions about their learning.

Enhancing Teacher Candidates' Technological Literacy and Self-Efficacy

Assignments in the science methods course incorporated digital literacies on a variety of levels. In terms of developing technological knowledge and skills, participants reported that the course assignments unquestionably impacted their technological literacy and self-efficacy (Skaalvik & Skaalvik, 2008) in a positive manner. Figure 1 illustrates TCs' responses to survey statements related to developing their technological literacy. It is evident that TCs felt that they learned about technology, how to use new equipment, and how to use new software programs or improve their usage of familiar programs. Some TCs experienced challenges, however, this did not dissuade them from seeking out peer and instructor support to become familiar with the equipment and programs and how to use them effectively in order to complete their assignments. One noteworthy finding is the fact that TCs felt that they learned to apply technology in teaching and learning. Furthermore, there was a positive trend towards using technology in their future practices. TCs' survey responses demonstrated heightened technological literacy in terms of digital competence (skills), digital usage (professional/discipline application), and digital transformation (innovation/creativity) (Belshaw, 2011).

TCs also reported affective outcomes including enhanced motivation, engagement, confidence, interest, and pride in their experiences with digital literacies in the science methods course. They felt confident in their own ability to plan, organize, and

Figure 1. Teacher candidates' responses to survey statements exploring technological literacy

carry out activities incorporating digital literacies to attain teaching and learning goals in science, as reported by TCs:

It just allowed me to see what the world of digital technology is actually like; it's complicated, but it's also not as intimidating as you'd think. I didn't know that much was available and out there and from the standpoint of understanding ... like actually being able to see what makes a good game for learning, and what makes a good digital application, not just for engagement, but for learning as well, and just seeing, understanding in myself that it's not difficult to recognize that sort of a thing, and I think just from having to go through so many concepts and trying to find resources and just even building a website, I think I can quickly find things better for my students ... now I know what I'm looking for, and I know what's available.

I learned a lot about different digital resources that I could use in my class, and I used a lot of them during my last practicum. So after being able to do my timeline and learning about Prezi, I was

always implementing it in the classroom, ... it was really useful as I learnt a lot of different software, a lot of digital media, and I became more literate. I feel very confident. I used it a lot. I was always showing them videos, playing games ...

Curriculum Development and Instructional Design

The inclusion of digital literacies offered TCs: 1) comprehensive and flexible resources in terms of design and accessibility; 2) organized, professional and aesthetically pleasing outcomes; 3) innovative means to differentiate and personalize instruction; and 4) a repertoire of digital teaching/learning tools. One TC commented,

It is very engaging, and kids nowadays are always on the computer anyway, it is a way to engage them, hook them in and get them ready. The technologies we explored in the science course were really exciting and I think the kids would really like that ... having them use Prezi, when they're presenting will really get them involved and interested. You always have those artsy kids that find

science very boring, and I think that would be a really good way to have them use their creativity to learn about science.

TCs also felt that digital literacies provide the affordance to personalize learning, as summed up by a participant:

A lot of the students I found were visual learners, so I think it benefits them most. They definitely get to see it, hear about the concepts, and if they have any questions they can see it again, and so basically, it's through visual learning that they benefit. Also, it's not just memorizing what is written in a textbook. They understand the concepts and they know how to explain them in their own words.

The sharing of multiple, varied representations of concepts helped TCs grasp complex material by showing them alternative forms of the same underlying idea (Rose & Gravel, 2012).

Challenges/Constraints to Implementing Digital Literacies

TCs cited a number of potential challenges to implementing digital literacies in the classroom, including the fact that teachers need to be trained in order to effectively utilize digital literacies and achieve success in terms of developing learning communities in the classroom. Several participants felt that digital literacies should be introduced in the lower grades, thus allowing students to become “more comfortable and confident when using these technologies” as students who are not “tech savvy” might be resistant to learning through “new” technologies. Another challenge is the variation in choice of digital literacies available; some teachers felt that “their choice of representation” did not always coincide with what was being promoted in their host school. Finally, access to computers was cited by participants as the greatest obstacle to implementing digital literacies.

FUTURE RESEARCH DIRECTIONS

Despite the fact that using digital technologies as part of the educational environment fits into the philosophy of active learning and constructivism, it poses a tremendous challenge for teaching and learning in different contexts, specifically those that may not have access or experience a “digital divide”. Consequently, a digital divide decreases an individual’s access to social opportunity. Thus, research that promote deeper understandings of where knowledge gaps exist in the research base around the impact of digital technology on teaching and learning is warranted. Findings, including gaps and barriers, will make significant contributions to our understanding of socially informed digital literacy and can inform educators, researchers, and policy makers as to benefits and challenges of implementing digital and technology based projects in different contexts.

CONCLUSION

The research study conducted with TCs reveal that integrating digital literacies in science teacher education can potentially impact TCs’ digital competence, digital usage, and digital transformation (Belshaw, 2011). Findings indicate TCs experienced enhanced technological literacy in terms of learning about technology, software programs, and equipment. TCs also reported affective outcomes including enhanced motivation, heightened self-efficacy, increased interest, confidence and pride in their experiences with digital literacies in the science methods course. Digital usage was evident in their course work and some TCs reported that they had implemented various technologies in their practicum. In terms of teaching and learning, digital usage was at the forefront as it introduced personalized learning pedagogy (Dede, 2014); promoted engagement; fostered learner choice and control; promoted 21st century learning skills; and highlighted the relevance and application of digital literacies in teaching and learning science.

Digital transformation, including innovation and creativity, was prevalent in their course work. The inclusion of digital literacies offered TCs i) the opportunity to design and create comprehensive and flexible curricular resources; ii) organized, professional and aesthetically pleasing outcomes; iii) innovative means to differentiate instruction; and iv) ample opportunities for knowledge construction resulting in a repertoire of digital teaching/learning tools such as digital timelines and multi-media interactive website resources.

In this study, TCs embraced a constructivist view and engaged in a knowledge construction process as they developed a learning community (Scardamalia & Bereiter, 1994); one that promoted, modeled, and supported digital literacies. Through the course assignments and practicum experiences, TCs were provided opportunities to locate and consume digital content, create digital content, and communicate digital content (Spires et al., 2012). Despite the successes, a number of challenges were identified in terms of implementing digital literacies in the classroom, including poor teacher preparation, a finding corroborated by Dipetta and Woloshyn (2009) who maintain that without appropriate training, educators will continue to use technology as a supplement to instruction rather than a tool to facilitate instruction. In addition, some TCs felt that there was disconnect between pedagogy related to digital literacies that they promoted and implemented during their practicum and digital competencies of host teachers, a challenge raised by Jewitt (2008) around knowledge construction thus affecting the development of learning communities. Finally, TCs felt that access to computers is the greatest barrier, a finding consistent with research (OECD, 2013), which maintain that despite the ubiquity to computers in the home, student access to computers at school is still limited.

By the end of the study, participants possessed a good understanding of digital literacies and ways to effectively incorporate them in their future teaching practices. There was evidence that TCs utilized digital literacies learnt in the

course during their practicum. Results indicate that the explicit integration of digital literacies created and engaged learning communities, while improving technological and scientific literacies in a purposeful manner. Results may contribute to the information available to educators and curriculum consultants about developing learning communities through the integration of digital literacies in teacher education through activities (e.g., digital timelines, websites, etc.); products of personal creativity that vary according to students' unique learning styles. Finally, the provision and use of digital literacies may assist TCs in helping students develop 21st century skills, enhance teachers' and students' scientific and technological literacy, and improve attitudes toward teaching and learning science in technology enriched environments.

KEY TERMS AND DEFINITIONS

C

Digital Divide: The gap between those with ready access to tools of ICT, and to the knowledge that they provide access to, and those without such access or skills.

Digital Literacy: A combination of digital competence (skills, concepts, approaches, attitudes), digital usage (professional/discipline application) and digital transformation (innovation/creativity).

Prezi: A cloud based presentation software that allows individuals to collaborate and edit presentations with multiple users. It allows students to construct and present their knowledge in different learning styles (videos, audio, etc.).

Socioscientific Issues: (SSI): Open-ended problems which are controversial social issues related to science and highlights the application of moral and scientific reasoning to real world situations.

Tiki Toki: Web-based software that can be used to create interactive timelines that can be shared on the Internet.

Designing Engaging Instruction for the Adult Learners

Karen Swanson

Mercer University, USA

Geri Collins

Mercer University, USA

INTRODUCTION

Instruction in higher education continues to follow a traditional model of instructor delivery and content focus. In a study by Nunn (1996), he found that less than six percent of class time involves student participation. There was no evidence of any instance in which students spoke for more than 23% of the total class time. A teacher-centered instructional method has received significant rebuke in the last decade, the stereotypical image is one of instructors droning on to a captive audience of undergraduates taking feverish notes for the sole purpose of reciting the information on a subsequent test. Hoyt and Perera (2000) surveyed faculty as to which type of instruction approach they incorporated into their practice. Forty-five percent identify some combination which used lecture as a primary approach. So the question then becomes what are the best practices for an engaging course design that benefits both faculty and adult learners?

Instructional design for the adult learner is a growing field of study in higher education. Engaging instruction for adult learners will be defined in this chapter in two ways: designing courses using the significant learning taxonomy, and a paradigm shift to support faculty to involve student participation.

Adult education is defined as “activities intentionally designed for the purpose of bringing about learning among those whose age, social

roles, or self-perceptions, define them as adults” (Merriam & Brockett, 2014, p. 8). The adult learner can also include those who are parents, working full time or older and more experienced than the traditional college student. Adults are motivated by learning that has a practical application and personal significance. In addition, the growing abundance of information makes covering a discipline almost impossible. So the alternative or anecdote to teaching a volume of information is to design the learning for significance in a complex and rich way. Here again the need to address student motivation becomes an issue to examine.

BACKGROUND

When planning instruction for adult learners it is important to examine their motivation for being in the classroom. They have chosen to pursue a higher education degree and the faculty’s challenge is to plan and execute engaging, relevant learning experiences. The traditional model of instruction in higher education, such as lecture and testing, while possibly engaging, is limited. If the goal is to be able to explicitly assess how students are making the connections among theory, content, and personal experience there needs to be a master course design. Fink (2007) explains that “our current instructional procedures are not working very well. Students are not learning even basic general knowledge, they are not developing higher-level

cognitive skills, and they are not retaining their knowledge very well. In fact there is no significant difference between student who take courses and students who do not” (Fink, 2013, p. 4).

Learner-Centered Instruction

Teaching adult learners should be focused on the learning process of the students. Teacher-directed instruction, such as lecture and rote memorization can be transformed to be more engaging through activities such as discussion and application.

Huba and Freed (2000) contrast teacher and learner-centered instruction as a model or paradigm. Their research shifts the focus from what faculty teach (content) to how students learn. They acknowledge that a teacher-centered methodology is not ineffective, but a shift from solely lecturing to a teaching style that incorporates more student interaction and a demonstration of learning beyond rote memorization which supports long-term retention. Huba and Freed (2000) characterize a teacher-centered paradigm in several ways:

1. Content is primarily delivered by the instructor and students are solely learners.
2. Content is not contextualized but rather students passively receive the information.
3. Assessment is the responsibility of the instructor, requires only rote memorization and is summative in nature.
4. Learning is the responsibility of the individual and courses can be constructed in a competitive nature (p. 5).

These characteristics may be more evident in large, lecture style courses where individual interaction is more cumbersome. However, the challenge is for faculty to begin to consider a possible paradigm shift towards learning centered instruction. Fink (2013) states, “...a major change already taking place in American higher education.....is a paradigm shift in which institutions are thinking less about providing instruction (the teaching paradigm) and more about producing

learning (the learning paradigm)” (p. 20). The following sections will explore this paradigm shift, how it impacts instructional design and how to engage students in this new perspective of learning.

Three Models: Transmission, Generative, and Transformative

As faculty, we design courses with a myriad of assumptions about teaching and learning. Those assumptions influence the decisions we make about how course time is used, assignments are structured and assessments are designed. Therefore, a theoretical background may provide a framework to place assumptions into a context for examination. Some assumptions that may be present include the student’s lack of prior content knowledge; more content is equivalent to increased rigor and time constraints (it’s faster to lecture). It may be assumed that teacher directed instruction requires less planning over time and is the format most appropriate in higher education. The objective of this section is to provide three general models to examine how moving towards learning centered instruction can produce rich educational experiences for the students.

Wink (2000) identifies three perspective models on teaching: the transmission model, the generative model and the transformative model. The transmission model has instructors filling students with information through primarily lecture and the students passively receiving information. The instructor controls the scope and sequence of information and evaluation is typically an examination which requires students to repeat information in the form they were given it (p. 121).

Researchers have come to know that students must construct knowledge from information which defines the generative model of teaching. This model provides a space for students to engage in the learning using groups to build on their own knowledge. Learning is no longer passive. The role of the instructor is to structure the course activities to guide students toward learning outcomes (p. 122).

The transformative model is a learner-centered classroom where students actively engage in determining the curriculum, activities and assessment of their understanding. The focus becomes application of knowledge to solving real-life issues (Wink, 2000, pp. 122-123). The examination of these models shows the paradigm shift toward learning centered instruction and challenges higher education instructors to find ways to engage students in the whole learning process.

A balanced classroom ebbs and flows between faculty delivery of information delivery and the students' application or demonstration of understanding. Palmer (2007) writes that there is a need to —rebalance the scales between an overemphasis on teaching technique and the value of the emotion of learning (p. 64). Palmer remarks that it behooves instructors to balance the rhetoric, to not hold too tightly to either possible polar position, but to use the best of each to enhance student learning. Palmer presents pedagogical attributes to creating an open learning environment.

1. The space should be bounded and open. Bounded refers to using a question, text or body of data to focus the class. The information should be very clear and compelling to attract student attention. Space is achieved through providing room for surprises, tangents and possibility to arrive at a destination not previously determined by the instructor.
2. The space should be hospitable and —charged|. Is this class a safe place to express my ideas? Is it hospitable? The charged element comes in the process of delving into compelling topics in meaningful ways where students can't marginalize or avoid the depths of new understandings.
3. The space should invite the voice of the individual and the voice of the group. Students should be expected to express their ideas regardless of how polished the presentation. True learning comes when students place their individual ideas in the company of

others. It is then that they are molded and stretched by the voice of the group.

4. The space should honor the little stories of the students and the big stories of the disciplines and tradition. This refers to the internal and external discussion between the individual ideas and the tradition of the discipline. If the individual is too present the discipline is lost, if the discipline is too present the process of internalization is compromised.
5. The space should support solitude and surround it with the resources of community. As with Baxter Magolda and Kings (2004) work on self-authorship in supporting students to become independent learning. Class time must incorporate time for students to consider material individually and also grapple with content interpersonally with their peers to make meaning.
6. The space should welcome both silence and speech. Silence can make instructors nervous. But silence is also a sign of reflection that is critical in the learning process. Instructors can specifically incorporate reflection points during or after class. (pp. 77- 79)

The image that emerges from Palmer's work shows instruction that spurs critical thinking as students become engaged in the process of the delivery of content. Again focusing on the learning aspect of instruction which includes both questioning and discussion topics. Although the instructor maybe in the front of the class leading this discourse, learning is still at the center of the lesson. Course design done well can create dynamic learning as well as promote the creation of independent learners.

Self-Authorship

The structure of a course can purposefully address each of these domains to expand the independence of students. The prior knowledge students bring to a course can be incorporated into the presenta-

tion of new information from a discipline. Done purposefully, the instructor can facilitate the acquisition and situation of new knowledge. They can also minimize the resistance by students to consider new perspectives regarding the subject matter. Individual and group assignments can be made for both during and outside of class time to create opportunities for students to grapple with new content. One theoretical framework to assist instructors to visualize how students learn and develop is Baxter Magolda and King's (2004) self-authorship model. They describe the process of cultivating sophisticated learners.

Educators try to make learning to fly as safe as possible, yet a certain amount of crashing is to be expected. Balancing the degree of risk during college with the necessity of expertise for adult life is a contrast learning curve in which educators sometimes crash and sometimes soar. (p. xvii)

Keegan (1994) defines self-authorship “as internally coordinating beliefs, values and interpersonal loyalties rather than depending on external values beliefs and interpersonal loyalties” (in Baxter Magolda & King, 2004, p. xviii). Briefly, they identify three domains in which students’ process information. The first is an epistemological foundation in which knowing is contextual built on a belief system that continuously evaluates, interprets and judges new information based on their prior knowledge. The epistemological domain wrestles with new information and the delivery person. Does the information and delivery blend with their current moral and intellectual conceptions or does it create a conflict?

The second domain, intrapersonal foundation, is how people view themselves and create an identity based on what they value and experience. This is the domain of individual reflection on learning which supports students making new connections. Examples of supporting coursework would be journaling, creating graphic organizers of their understanding of connections, or reading the text using marginalia to create dialogue with the author.

The third is the interpersonal domain where students place their identity or knowledge in context with other students and instructors (Baxter Magolda & King, 2004, pp. 8-9). The interpersonal domain provides a learning centered instructional model where information or ideas are presented by students working with others to make sense of that information as a group. For example, study groups or group projects would require students to determine how their ideas fit with others and promote a creation of new understandings that would not have been possible individually. Therefore the bridge between supporting adult learners to develop self-authoring behaviors is embedded in creating significant learning experiences.

The bridge between tradition and innovation may be found in learning outcomes that promote self-authoring. Fink (2013) has created a course design structure called significant learning experiences. Significant learning experiences are defined as teaching that results in “a learning experience resulting in something that is truly significant in terms of the students’ lives” (p. 6). The goal is to focus on process and outcomes that result in the following four characteristics:

Process

1. **Engaged:** Students are engaged in their learning.
2. **High Energy:** Class has a high energy level.

Results, Impact, Outcomes

3. **Significant and Lasting Change:** Course results in significant changes in the students, changes that continue after the course is over and even after the students graduate.
4. **Value in Life:** What the students learn has a high potential for being of value in their lives after the course is over, by enhancing their individual lives, preparing them to participate in multiple communities, or preparing them for the world of work. (Fink, 2013, p. 8)

The transition from the characteristics of significant learning experiences is to evaluate or section a syllabus or course design into three types of learning. The first is the *delivery* of content to provide a foundation for subsequent higher order activities. Content can be obtained through readings, lecture, or online modules to name a few. These activities can incorporate both teacher-directed and learner-centered methods. The second section is to outline the *process* elements. These would include presentations, designing prototypes, community experiences, and other similar authentic experiences. The final section is for students to *evaluate and reflect* on their learning experience and for faculty to assess their work (Fink, 2007). The scaffolding of student learning and course construction is vital to engaged student participation and readiness for class.

Fink (2013) uses a Taxonomy of Significant Learning to address areas instructors may find useful as they design instruction that motivates learning:

1. Foundational Knowledge provides the basic understanding of broad subjects that is necessary to create knowledge for learning in multiple content areas. For example, an understanding of historical events such as the Revolutionary War, Civil War, Civil Rights, etc.
2. Application allows other kinds of learning to become useful for example in the use of knowledge to perform a task. Application is evidenced in critical thinking and problem-solving.
3. Integration is making connections between and among concepts or ideas.
4. Human Dimension informs students about the human significance of what they are learning. This is similar to Baxter Magolda and King's (2004) self-authors model that empowers the student to alter their internal conversation and what they know about themselves.
5. Caring. When students care about something, they then have the energy they need for learning more about it and making it a part of their lives. Without energy for learning, nothing significant happens.
6. Learning how to learn is when student understand the strategies of how to learn independently such as reading strategies and writing patterns. It enables students to continue learning in the future and to do so with greater effectiveness (pp. 39-40).

These areas become the foundation for learning centered instruction and the underlying theme is motivating students in the classrooms.

Instructional Design

Good teachers possess a capacity for connectedness. They are able to weave a complex web of connections among themselves, their subjects, and their students so that students can learn to weave a world for themselves. The methods used may vary widely: discussion, questioning lectures, Socratic dialogues, laboratory experiments, collaborative problem solving, and creative chaos. The connections made by good teachers are held not in their methods but in their hearts “meaning *heart* in the ancient sense, as the place where intellect and emotion and spirit and will converge in the human self” (Palmer, 2007, p.11).

In a powerful learning experience, students will be engaged in their own learning, there will be “high energy level associated with it, and the whole process will have important outcomes or results (Fink, 2013, p. 8). The idea of the faculty/student relationship is important to explore. It is important to connect with students in order to have them want to engage in the process of learning. The connection must be professional and intellectual. It is important to always relate the knowledge without being the end all on any given subject. Allow students to disagree with what is stated and then discuss the differences that are in question. This gives students the ability to connect

Figure 1. Fink's significant learning experience taxonomy (2013, p. 35)

in a positive way and learn how to view different perspectives. If students are invited to take the risk of speaking their mind, teachers must be able to guide the discussion without being intimidated by the student's perspective. This two-way street gives the attitude of professionalism and intellectualism to the classroom environment. Students learn how to use their voice in a professional way and learn from the acceptance of the teacher. "Both artistry and technical skills are required as you develop presentation techniques that are well fitted to your unique instruction circumstances" (Savage, Savage & Armstrong, 2006, p. 242).

Once more, a level of rapport must be developed between the teacher and the students. Classroom with this kind of instruction become active learning environments. Content can either be dry and boring or exciting and interesting. Humor is a good way to engage students and can lead to understanding if connections are made even if they are funny. "Enthusiasm is contagious. If you express a high level of interest and sense of importance about

your topic, students often become spellbound, anxious to find out what so interesting" (Moore, 2009, p.150). The whole environment of the classroom revolves around how well the teacher can ignite interest in the subject and help the students to become a part. Adding points of interest that capture the meaning of a concept gives student a way to remember what needs to be learned. The demeanor of the instructor during lecture is important as well. The speaker should smile, make eye contact with student when they ask questions and move around the room to better include all students (Sullivan & McIntosh, 1996, p.7). Moving about the classroom also adds a physical connection that keeps students aware that something is actually happening in the classroom.

Student Engagement

The shift for higher education faculty is to plan with the end in mind. Faculty redesign their delivery to engage students with them in the process

of learning rigorous content. It brings the words being spoken to life and relays the importance of what students need to know. A well-prepared class must move beyond the required reading, lecture and test model. The questioning and discussion regarding the reading can be ways for students to give their perspective. Student reflection can move the lecture to more depth as analysis is used to present the information. As lectures evolve, students begin to understand the broader aspects of what they need to understand about any given subject (Brookfield, 2005). It is also important to acknowledge the students contribution to the lecture. Moore (2009) refers to this as reinforcement, "...rather than give reinforcement early in the questioning sequence, you should allow as many students as possible to respond to the question then reinforce them for their contribution" (p.163).

Two methods to create accountability for students to come to class prepared to discuss readings include student created reading cards and reading panels. The reading cards are 3x5 cards which students prepare notes using the assigned readings for week. The cards are turned in the first five minutes of class, usually left at the door in a basket. The instructor puts a special stamp on those turned in on time (late comers loose out) and students can use stamped cards on the exams. Another strategy is to create a reading panel. Student names are put into a hat and five names are drawn each class. Those five students are responsible to be prepared to lead a discussion of the reading without the assistance of the instructor. Each week names are drawn, all the names are available each week, so that once a student participates they are not out of circulation hence stop reading.

The classroom should be a two way street, this means that students also have a responsibility for their learning by coming to class prepared. Faculty "must focus on changing the role of the student from passive observe to active participant. In this approach, the responsibility for meeting learning

objectives is shared by the instructor and each student" (Sullivan & McIntosh, 1996, p.5). Student preparation includes reading information and involves in-depth analysis of what is read which increases the student's ability to express their perspective in class. Students should not hesitate to raise questions; the interruption forces the instructor to engage with the students. If students take the challenge to insert themselves into the lecture with questions or comments they encourage others to join the discussion. Teachers must be open to let students become involved, but it is as important for students to be prepared as much as it is for the teacher.

Questioning

Questioning is one of the best ways to engage students. However, questions only engage the students if they lead to more discussion. Open-ended questions provide students the opportunity to think and give them ownership of the discussion. The use of focus questions can inform instructors what students know and create interest in the topic. Questions which "may be factual, empirical, productive, or evaluative are used to direct student attention" (Moore, 2009, p.158). Questioning is a skill that teachers need to acquire. Part of the technique is using wait time which is a purposeful delay to fill the quiet space created when students are forming a response. Instructor pacing generally allows for a one second wait time; however when wait time is increased to three to five seconds Moore (2009) found:

1. Student response time increased.
2. Failure to respond tends to decrease. Student asked more questions.
3. Unsolicited responses increased.
4. Student confidence increased (p.162).

Wait time allows student time to think and again, engages them in the lesson. The question needs to invoke the thinking process and lead

to more in depth discussion of the subject. One questioning technique that is highly used is the Socratic Method which Paul and Elder (2007) describe as:

disciplined questioning that can be used to pursue thought in many directions and for many purposes...The key to distinguishing it from other types of questioning is that Socratic questioning is systematic, disciplined and deep and usually focuses on foundational concepts, principles, theories, issues, or problems. (p. 36)

The objective is for discovery on the part of the students to understand the concept being examined, the idea being explored, the process being described or the content being explained. The faculty and the students become involved in a dialogue which allows the students to see different perspectives as they begin to form their own ideas based on a broader understanding of the elements being presented.

Lecture Recitation

Lecture recitation is another method that can be effective and also efficient. Moore (2009) points out the use of a lecture formed around questioning adds another dimension to the instruction. The time spent giving needed information should always be as engaging as any hands-on activity. Lecture recitation helps to invite students into a conversation. The faculty becomes the director of the concepts being discussed and leads the flow of information towards the desired content. Discovery is the purpose for students as they formulate their answers to open ended thought provoking questions. The whole class can participate as the instructor directs questions that pique the interest of each student. All answers must be accepted and used to continue the discussion which adds depth to the content being studied. Students are equally responsible to come to class prepared with readings and homework complete to best participate with their peers.

FUTURE RESEARCH DIRECTIONS

C

As previously stated, "...a major change already taking place in American higher education.....is a paradigm shift in which institutions are thinking less about providing instruction (the teaching paradigm) and more about producing learning (the learning paradigm)" (Fink, 2013, p. 20). The long-term outcomes for higher education appears to be shifting towards graduates who are critical thinkers, collaborative, flexible and creative. While content is essential for a well-rounded and informed person, it is the higher order thinker who will be successful to the future workplace.

This is a challenge for faculty who love their content and love being the expert. There will need to be a new way to matriculate new faculty to begin thinking more about learning. There must be professional development for current faculty to realize that the transformation of their syllabi, teaching and assessment is a process towards a new paradigm, rather than throwing the baby out with the bath water. Faculty enjoy seeing student reactions when they grasp a concept or a skill, the future of teaching and learning in higher education will be to design for those significant learning experiences from the beginning.

CONCLUSION

The need to examine how to provide engaging instruction for adult learners is the rationale behind this study. The investigation revealed adult learners' desire to obtain more in depth instruction which requires a paradigm shift towards learning centered pedagogy. The basic themes presented in the new paradigm addresses how to motivate the adult learners, how to design engaging institutions to enhance motivation and how to focus on learning centered instruction which invites students to participate in the learning process there by gaining ownership of the learning. This study gave suggestions for actual classrooms instruction as well as ways for instructors to entourage different ways

of learning. It was the intent to provide theoretical background for the paradigm shift and also way in which to implement different strategies to create learning centered instruction.

KEY TERMS AND DEFINITIONS

Adult Education: “Activities intentionally designed for the purpose of bringing about learning among those whose age, social roles, or self-perceptions, define them as adults.

Self-Authorship: Refers to a phase of development within the lifelong process of self-evolution.

Significant Learning Experiences: Defined as teaching that results in—a learning experience resulting in something that is truly significant in terms of the students’ lives.

Educational Ontology Development

C**Galip Kaya***Havelsan Inc., Turkey***Arif Altun***Hacettepe University, Turkey*

INTRODUCTION

Amount of data on the web is constantly growing day by day and it is a new skill to be developed for users to reach the information for their needs, tasks and/or goals among vast amount of information. Likewise, in educational domain, it is a big challenge for teachers and learners to find educational resources on the web and to be sure that these resources meet their requirements. Semantic web technologies, including ontology use, offer a solution for those problems to be solved within educational domain by using domain ontologies.

Ontology provides a framework to determine a domain of interest and to build a common understanding in this domain between different applications by representing concepts and relationships that exist between these concepts. Ontology use in education environments can be explained in three main groups: content access and/or retrieval, content creation, and personalization. Use of ontologies also helps content creators to design and develop online courses; provide smart searches and content suggestions; and, design personalized learning environments for learners. All these advantages come with a price, though: It is not always possible for educators to find the best ontology for their needs in their Learning Management System (LMS). Consequently, users generally have to create their own ontologies from scratch.

In developing an ontology, there is no single and/or standard method to follow that can be ap-

plied to all domains since they are widely differ across domains as in law, medicine, information technologies, education, military etc. Since the ontology creation is a complex process, it might not be always easy or even possible to create an ontology for a selected domain and use it across domains.

To address these concerns, in this paper, first, a review of state-of-the art literature regarding the ontologies in educational domain will be reviewed. Second, the challenges and difficulties in ontology development process for educational domain will be addressed and explained in detail. Finally, design suggestions to the difficulties expressed in the literature and further opportunities in ontology design and development will be presented taking the existing ontology evaluation frameworks into account.

BACKGROUND

Approaches to Ontology Development for Educational Purposes

There are several classification methodologies when developing ontologies in education, among which are domain-task, task, and domain ontologies (Breuker, 1999; Devedzic, 2004; Allert et al., 2006; Al-Yahya et al., 2014). Based on their purposes, we can categorize educational ontologies in three groups:

- Ontologies for content access (Aroyo et al., 2002; Mitrovic & Devedzic, 2004; Lemnitzer et al., 2008; Lama et al., 2012; Solomou et al., 2015),
- Ontologies for content creation (Simon et al., 2004; Neto & Gauthier, 2006; Boyce & Pahl, 2007; Oprea, 2011; Manganello et al., 2013; Çelik et al., 2014)
- Ontologies for personalization (Henze et al., 2004; Karampiperis & Sampson, 2005; Fok, 2006; Vargas-Vera & Lytras, 2008; Chen et al., 2011; Clemente et al., 2011)

In the following section, each of these groups will briefly be described.

Ontologies for Content Access

Content access is usually related to providing an access to the existing content within the curriculum in a domain. The main assumption is to list all the standards/goals in a specific course curriculum and map the ontology to these standards accordingly. In their ontology development, for example, Al-Yahya et al. (2014) have designed a curriculum ontology named CURONTO. In their research, they used CURONTO to manage and assess the existing curriculum to provide feedback to the teaching program. They also claimed that, their ontology model is used to establish relations between goals, learning process and the curriculum so that the related stakeholders could benefit from querying the ontology to monitor to what extend the curriculum is aligned with their existing goals and learning processes.

Some researchers took the curriculum model a step further by integrating a user model within the ontology. Clemente et al. (2011, 2014), for example, created a student model by using the ontology as a knowledge representation model. In their ontology, student's cognitive process is taken into account so that with use of ontology, a link is created between student's cognitive process, knowledge and teaching goals. The overall system included three ontologies working in line with

each other. First one, student profile ontology, is used to keep personal information; second, student state ontology is used to track learning process of student; and, learning objectives ontology is used to assess learning outcomes.

Ontologies for Content Creation

Çelik et al. (2014) created an ontology based agent-based Educational Activity Discovery System which is designed to propose educational methodologies for parents or educators about pervasive developmental disorder. They used OWL to build knowledge base and created an ontology of pervasive developmental disorder with concepts and relations of this disorder. By the help of ontology, the system allowed educators to create semantic searches and to support their teaching processes.

Karkar et al. (2014) proposed an educational system for children with intellectual challenges, by creating multimedia tutorials for children dynamically. Researchers used several techniques to create tutorials, such as natural language processing, text extraction, ontology usage and online content retrieval. Researchers went further to claim that their system could dynamically customize learning content by taking learners' preferences into account. Ontology of the system is built from scratch and SPARQL queries are used to list and propose multimedia content.

Marzano and Notti (2015) used ontologies for educational assessment, to assess the system and learning in particular. They created a learning environment in their previous study named EduOntoWiki. This environment is aimed to create an ontology based repository for learning objects. Users of this environment can create content by using ontological structures. EduOntoWiki is used as a test environment for educational assessment in this research. They finally stated that with this approach of educational assessment, it is possible to use different methodologies and models in order to assess systems automatically in an efficient and effective way.

Solomou et al. (2015) have proposed a specialized ontology based version of IEEE LOM standard to use in any e-learning environment to improve discovery and retrieval rates of the educational materials. They called this profile as educational metadata profile (EMP). They further stated that, EMP could effectively describe educational and technical parts of a learning object. By use of this ontology as a basis for EMP, semantic relationships between learning materials can be defined. EMP is used in a distance course on object oriented programming by incorporating learning objects when delivering the online course from a distance. Finally, the researchers concluded that with EMP, learning objects could successfully be retrieved even if the selected concept is not directly stated in the knowledge domain.

Ontologies for Personalization

Kaya and Altun (2011a) proposed an ontology based learner model for e-learning systems. Researchers stated that, although there are standards of consortiums like IEEE (Personal and Private Information, PAPI) or IMS (Learner Information Package, LIP) that provide learner models, these models are very complex to use in real applications. Therefore, researchers have proposed new learner/user models for educational and/or other adaptive systems. This user model included Demographic information (learner related demographic information); current learner status (learner's current knowledge about the domain); expectations (learning goals which learners are expected to acquire, will be provided by the curriculum ontology); individual attributes (individual related data such as cognitive attributes, learning styles, presentation types etc. will be kept); performance (completed courses, resolved tests, progress status, achieved gains and other results which emerge in the interaction of system and learner) and context attributes (technical data such as connection speed, operating system of learner etc.)

Cakula and Sedleniece (2013) proposed an ontology based personalized e-learning model that

uses basic elements of personalization: Student personality, knowledge level, course content and technologies. They explained adaptation of knowledge management for e-learning, learning object as used for basic building blocks of e-learning and metadata used for learning object access. Ontology and semantic web use is also explained in this research, and with this approach, researchers propose that ontologies support semantic search and it is possible to make smart queries from multiple repositories by creating connections to learning objects with ontologies.

CHALLENGES AND DIFFICULTIES

Despite building educational ontologies has its own challenges and difficulties, education domain shares same issues with ontology development in general ontological engineering area. First of all, most of the ontologies are created using OWL DL ontology language and for most of the researchers who are new to ontology creation, it is hard to understand formal description logic (DL) language in OWL DL. DL is a union of formal knowledge representation (KR) languages based on first-order logic and is based on a formal, logic-based semantics (Baader and Nutt, 2003). First-order logic can express structures of a theory in a finite domain (which can be identified as problem domain). Users also shall have a knowledge of open world reasoning to understand DL. Because it is necessary to understand and implement all rules of DL to implement an ontology in OWL DL, ontology developers usually suffer in realizing all these rules in their ontology.

Another ontology creation issue is related to reusing existing ontologies. Despite there are several methodologies exist describing ontology generation from scratch (Uschold & Gruninger, 1996; Fernández-López, 1997; Noy & McGuinness, 2001), there is no single formal methodology that describes how to reuse existing ontologies or how to incorporate other existing ontologies into a new one. Although some researchers encourage to

reuse existing ontologies (i.e., Borst, 1997; Pinto & Martins, 2001; Park et al., 2011; Kalfoglou & Schorlemmer, 2003), lack of an existing and working model makes it difficult to incorporate the existing one into new domains. Therefore, starting from scratch becomes a preferred method, which results in more time and effort. More importantly, when aligning (mapping, merging, integration) ontologies across domains, besides using the same (similar at least) relationships inside domains, it is an issue to use existing relationships that connect and combine different domains (Noy & Musen, 2000; Pinto & Martins, 2001; Kalfoglou & Schorlemmer, 2003; Choi et al., 2006). Also, aligned ontologies shall answer the queries consistently. Thus, after aligning different consistent ontologies, the new created ontology shall remain as consistent in their structure.

There are also several pitfalls in ontology development (Poveda et al., 2009b) such as, using synonyms as classes, defining relationships as inverse even if they are not, recursive definitions, polysemy, using “is” relationships, defining classes entailing other classes, defining relationships out of current development domain, incomplete information. For example “is-a” or “part-of” relation describes only the inclusion of a relation between concepts. Using just these relations eventually turns the ontology into a taxonomy with a hierarchical structure. Thus, power of ontologies to represent the domain relationships cannot be realized thoroughly (Mansur & Yusof, 2013).

In educational domain, several concepts are combined to stand for a new concept. So it is a challenging task to define these concepts and relations across domains. It is also harder to infer meaning from new combined concepts. For example, in math, a function could be represented in multiple forms; whereas, a function is usually considered as a relationship in liberal arts. Once developing the ontology for educational domain, educators are challenged to represent such concepts whether they are concepts or relationships.

Another problem is about using automated ontology building technologies by using textual materials. In this process, all the concepts, restrictions, and relations are extracted from a given text. Since the natural language processing and text extraction methodologies are not perfect yet, all the remaining post processing work need to be completed by ontology engineers. Since this creates a very challenging and time consuming job, it is generally neglected and development process starts with various limitations.

DESIGN SUGGESTIONS

As the ground zero of ontology development is using OWL DL, the first suggestion would be related to the clarification of OWL usage. Rector et al. (2004) has once listed the most common errors and problems about OWL DL in detail and have also suggested solutions about these issues. Solutions of using OWL starts with using the disjoint axioms. Ontology developers need to be familiar with reasoning and formal logic before starting development with OWL DL, otherwise, it will be harder to design an ontology leading to a faulty logic. Furthermore, domain and range constraints should also be carefully defined so that inconsistencies become minimized.

Design patterns consists of shared guidelines to help minimize the design problems. Design patterns are commonly used in software engineering and is also used in ontological engineering to solve common problems. Svatek (2004), Gangemi (2005), De Cea et al. (2008), Gangemi & Presutti (2009), Blomqvist (2009) explained ontology design patterns (ODP) in detail. ODP help users solve ontological design problems and help in modelling ontologies (Poveda et al., 2009a). An example ontology design patterns is partition design pattern. In this pattern, a concept is considered as partition. Another approach is to use the worst practices (Poveda et al., 2009a). Worst practices in ontology design process are listed as using recursive relations, lazy elements,

Table 1. Differences of educational ontology development methodology

	Noy and McGuinness (2001)	Kaya and Altun (2009)
Step 1	Determine the domain and scope of the ontology	Determine the domain and scope of the ontology due to subject matter of educational domain
Step 2	Consider reusing existing ontologies	Consider reusing existing ontologies
Step 3	Enumerate important terms in the ontology	Enumerate important terms in the ontology, considering educational domain and relation of these terms to other terms in other domains
Step 4	Define the classes and the class hierarchy	Define the classes and the class hierarchy due to subject matter of educational domain
Step 5	Define the properties of classes (slots)	Define the properties of classes, considering educational domain and relation of these classes to other educational domains
Step 6	Define the facets of the slots	Define the facets of the slots
Step 7	Create instances	Create instances

undefined inverse relations, and defining classes instead of individuals, etc.

Authors of this paper have reviewed basic ontology development methodologies (Uschold & Gruninger, 1996; Fernández-López, 1997; Noy & McGuinness, 2001), and implemented Noy and McGuinness (2001)'s methodology to create an ontology for educational environments (Kaya & Altun, 2009). As Noy and McGuinness' model for ontology development is mostly suitable for educational ontology development, authors updated some steps of this methodology to make it a more suitable development model and proposed an updated ontology development methodology as one of the results of paper. Differences are given in following table:

One of the main problems in educational ontology development is related to the concept representation. Since concepts are highly dependent on the subject matter, it is not quite easy to apply a standard methodology for extracting concepts from a subject domain. Likewise it is an issue to clarify hierarchies of classes and relations (e.g. slots and facets in ontology) between concepts. Hierarchy of educational concepts often requires multiple inheritances which make inferencing instable within the ontology. So, determining hierarchy of classes in educational domain requires a common consensus across content experts.

Noy and Musen (2000) suggested to use mediators in ontology when reuse and/or integration is preferred. Mediators (Wiederhold, 1992) can answer questions about an information source. Thus, each information source shall have an interface between itself and the mediator. Within this framework, a common data model could then be created by incorporating the information sources and required targets to attach to the data model. As a result, matching rules will be defined so that the sources could be translated into the target; in other words, queries could be executed over these rules. To sum up, it can be concluded that educational environments needs the following fundamental ontology types:

- Domain ontologies, contain information about current domain, holds information about concepts, relationships, restrictions etc. about whole domain.
- Curriculum ontologies, contains information about whole curriculum. This ontology shall reuse several domain ontologies to build an entire curriculum e.g. for a lesson.
- User/learner ontologies, contains information about user, user's development, current information, progress of user, completed or studied materials of user.

All these ontologies will contain concepts, relationships and restrictions within their own domains. It is hard to build ontologies from scratch that covers all the limitations into account. Sometimes ontologies can contain or include other ontologies, and as stated above, there is no standard procedure for users to merge ontologies and use them in cooperation.

Finally, ontology evaluation is another challenge to deal with. Groza et al. (2014) presented a specification of Ontology Building Competition 2013, by providing a set of metrics to be used to evaluate ontologies. The metrics covered five dimensions: Structural, semantic, design patterns, worst practices and capability to answer to competency questions. In structural evaluation, concept and attribute richness are measured. Concept richness is ratio of non-empty classes to total number of instances. Attribute richness measures quantity of information that is held by an individual. Modularization and connectedness measure the reuse of information in an ontology such as the reuse of other ontologies in current ontology.

In semantic evaluation, it is assumed that it is better if an ontology has more expressive logic. In this evaluation consistency and coherence metrics are emphasized. Domain coverage, on the other hand, is evaluated by answering predefined competency questions and predefined terms.

Another ontology analysis based on design patterns is developed by Poveda et al. (2009a). Researchers explained patterns and anti-patterns by illustrating how anti-patterns could be used as an ontology analysis method. Researchers created a decision tree to classify patterns, anti-patterns and worst practices. When deciding which analysis method is the most effective one, first, it is checked whether a design pattern is used when creating the ontology. Secondly, similar step is taken to check whether design fits into anti-pattern. Finally, it is checked whether any of the worst practices in ontology design is observed in the existing ontology. Some of the worst practices in ontology design is listed and finally worst practices when

creating the relationships in ontology are provided to researchers.

Ontologies can also be compared by using precision and recall parameters which are widely used in information retrieval literature with F scores (harmonic mean of these parameters). These parameters are used in evaluation of ontologies (e.g., Khan et al., 2004; Nagypal, 2005; Shehata et al., 2007, Lemnitzer et. al., 2008) and discussed in detail in Kaya and Altun (2011b). Precision is the rate of retrieved document count to total document count, recall is the rate of retrieved relevant document count to total relevant document count either retrieved or cannot be retrieved. F score is harmonic mean of precision and recall values. This methodology can be applied to concepts addressed by ontologies, and number of concepts in ontologies can be used instead of document numbers. As a result of these calculations, precision, recall parameters and F scores can guide developers to decide which ontology could be preferred.

CONCLUSION

In this paper, literature of educational ontology use is reviewed and some of the basic problems for educational ontology development are addressed. Based on educational ontology literature, ontology development process and ontology evaluation techniques have been discussed and synthesized. Furthermore, some suggestions were provoked based on the reported issues and experienced problems and challenges.

FUTURE RESEARCH DIRECTIONS

Use of ontology development design patterns can be used in educational ontology development process, as described in “Design Suggestions” section. But as these blue prints are generally created for ontology development for all domains, educational ontology developers need to be more

specific when developing and applying design patterns and solutions in their future research.

As the ontology development is a very complex process to start from scratch, automated or semi-automated development methodologies are required. By the help natural language processing and data mining methodologies from computer science literature, ontology development process could be elaborated and hopefully more educational ontology-based applications will be utilized.

In evaluating the existing ontologies, researchers tend to apply measures to observe how content is accessible in accurate and fastest way. When ontologies are introduced for educational purposes, on the other hand, educators are also very interested in whether the content created an opportunity for learners to better grasp the provided content. To design an experimental research to observe this effectiveness is also a challenging task. Therefore, more research is needed to measure the effectiveness of existing ontologies across or within a domain.

KEY TERMS AND DEFINITIONS

Design Pattern: Design patterns consists of shared guidelines helping design problems. Design patterns commonly used in software engineering and is also used in ontological engineering to solve common problems.

Ontology: Ontology provides a framework to determine a domain of interest and to build a common understanding in this domain between different applications by representing concepts and relationships that exist between these concepts.

Personalization: Personalization is adapting learning experience to different learners due to the analysis of knowledge, skills and learning preferences of individuals.

Semantic Web: Semantic web defines data and relations of the data significantly so that a common knowledge base will be provided among applications and more efficient search, integration and reuse operations will be provided. Semantic web provides an environment which human and machines can communicate.

Factors Contributing to the Effectiveness of Online Students and Instructors

INTRODUCTION

As technological advances become mainstream in higher education, web-based learning continues to gain focus and momentum. The number of online courses in K-12, technical, professional and liberal arts education has increased significantly (Allen & Seman, 2013; Picciano, 2001; Setzer & Lewis, 2005). Multimedia technology has changed the landscape of distance education (Zirkle, Norris, Winegardner & Frustaci, 2006). Gray (2013) purports barriers to online learning are being addressed and students have access to more educational opportunities than ever before.

Online learning programs often tout more interactive, individualized and independent learning (Chen, Czerwinski & Macredie, 2000; Inan, Yukselturk & Grant, 2009; Park & Lee, 2003). However, a major challenge with web-based learning is identifying the idiosyncrasies between learning online and the traditional learning format (Inan, et. al., 2009; Martinez, 2003; Rovai, 2003). Another challenge is identifying the very different profile of online students (Dutton, Dutton & Perry, 2002; Sikora & Carroll, 2003).

Identifying the positive attributes of students and instructors in the online environment will contribute to the understanding of how we can enhance the learning experience for the student and the teaching experience for the instructor. This article will assist students and instructors

in understanding the differences that may be experienced in the online environment versus the face-to-face environment and provide the opportunity to consider whether online learning and/or teaching is a “good fit” for them. Understanding why students and/or instructors might choose the online environment will also assist administrators in developing successful, quality online programs that enrich the experiences for both students and instructors.

BACKGROUND

In 1981, the first online classes were developed at the School of Management and Strategic Studies at Western Behavior Sciences Institute in La Jolla, California. An evaluation of the program, and the discussions that took place, revealed that the quality of the online course was higher than the information collected in the traditional classroom setting (Feenberg, 1999).

Since that time, a number of studies have compared the effectiveness of online instruction to traditional lecture formats. Findings have admittedly been mixed (Rivera, & McAlister, 2001; Ungerleider & Burns, 2004; Zhang, 2005). Even though a majority of the studies find no difference in student performance and student satisfaction, regardless of the delivery format (Lim, Kim, Chen & Ryder, 2008; McFarland & Hamilton,

Figure 1. Motivations to take online courses

2006), there is concern regarding online student retention. Knowledge of student characteristics and how they can possibly affect online course success can provide the opportunity for faculty to intervene before grades are affected or dropout rates increase (Cochran, et al., 2014).

Kilburn (2005) developed the following conceptual map regarding student motivations to take an online course at a particular University in the Midwest. (see Figure 1)

CHARACTERISTICS OF SUCCESSFUL STUDENTS AND INSTRUCTORS

In the upcoming section, an examination of student and instructor characteristics and how each of those different roles contributes to the quality of an online course will help provide insight into the foundational underpinnings of web-based learning.

Student Characteristics

It is estimated that five out of six students taking an online course are employed and would not be able to attend traditional classes (Thomas, 2001). Literature suggests that the growth in online courses is based on attracting new students rather than “stealing” from students enrolled in

current on-campus programs (Mangan, 2001, Thomas, 2001). Kauffman (2014) points out the convenience and flexibility that online education affords students with work and family demands. Undergraduate online students are commonly older, married, or have dependents (Dotterweich & Rochelle, 2012). Regardless of gender or age, students who need the flexibility of online or distance education classes in order to obtain a degree may find online to be a good option for them (Dotterweich & Rochelle, 2012).

Kilburn (2005) found that positive characteristics identified in studies stress the importance of an active versus passive student role in an online course. Some researchers have attempted to identify student abilities that suggest whether a student will complete an online course, or be less satisfied with an online course, in comparison to the traditional classroom setting. In Kirmizi’s study (2015), student satisfaction was used as the dependent variable and sub-dimensions of a learner’s readiness: computer self-efficacy, self-directed learning, learner control, motivation, and online self-efficacy, as the independent variables. Kirmizi identified self-directed learning as the most valuable predictor of success, with learner control and motivation as next in importance. Shea and Bidjerano (2010) also suggested that motivation, self-efficacy, and self-regulation are the central components of learner presence in an online course. Studies have consistently reported

students need to develop self-regulatory abilities and take control of their learning (Dabbagh & Kitsantas, 2004; Picciano, 2001; Rovai, 2003; Saba, 2000).

One attraction to online learning is the presumed capacity to increase access and equity to learners by removing some of the barriers to participation (Harasim, 1990). Sullivan (2001) found that students appear to find the online environment more welcoming for quiet and shy students than the traditional classroom. Varela, et. al., (2012) found that low gregariousness and achievement orientation were able to predict learning. In another particular study, using the Myers-Briggs Type Inventory, almost half of the online students surveyed were introverts, sensors, or judges (Mupinga, Nora & Yaw, 2006). Online students also may not be as comfortable working in groups and prefer the more individualized environment that online courses can provide (Haigh, 2007).

Sullivan (2001) asserts that nontraditional students, particularly female, adult learners with children or familial responsibilities, value online courses. Research has suggested that the asynchronous nature of the online environment might encourage a more reflective type of interaction that changes the dynamics of classroom discussion in a way that female students find rewarding (Selfe, 1999). Arbaugh (2000) found that males communicate online in a more competitive manner, while females viewed Internet-based communication as a medium to develop collaborations in online learning. It should be noted that some studies reported differences between genders (Wladis, et al., 2015; Dotterweich & Rochelle, 2012; Yang, et al., 2011) while others did not find significant differences (Lim, 2001). Regardless of gender, students often benefit from online courses because of the ability to balance work and family, among other convenience factors (Al-Asfour & Bryant, 2011). While Wladis et al. (2015) discovered both men and women performed worse in online science, technology, engineering, and mathematics courses, they did not find a significant difference in regards to the online medium and ethnicity. At

some institutions the push to offer more online courses is promoted in order to reach populations who have not had access to higher education because of social or geographical barriers (Enoch & Soker, 2006).

The age of a student in relationship to course completion rates has been an area of focus in current research. Some research suggests that students over 30 and under 50 years old are more likely to choose and finish a distance course than traditional students age 18 to 29 (Cao, et. al., 2011; Sikora & Carroll, 2003). Other studies have generated mixed results. Xenos, et al., (2002) found a positive correlation between age and dropout rates. Jones et al. (2004) suggested that as students get older, more dropouts are likely to occur. In contrast, Cochran et al. (2014) found freshman to have the highest rate for online course withdrawal, with a steady decrease as class rank increases.

Students should possess the ability to navigate the Internet and deal effectively with computer software and hardware difficulties. Technological difficulties and “feeling lost in cyberspace” were cited as negatives by students (El Mansour & Mupinga, 2007). Motteram and Forrester (2005) suggest the first hurdle students struggle with in the online environment is becoming familiar with the computer (i.e., how to access, enter and navigate sites).

In the online environment, successful students shift from a more passive role in the exchange of knowledge to a more active role. Several studies purport that the following are the most influential factors affecting a student’s active participation in online learning: (1) prior knowledge of online learning, (2) knowledge of a given subject area, (2) strategies to cope with information overload, (3) personality traits, (4) instructor facilitation, and (5) appropriate feedback (Vonderwell & Zachariah, 2005). Koohang’s research suggests active learning has three essential stages – the underpinning state, the ownership state and the engaging stage (Koohang, 2012 & Koohang, et. al., 2013).

Instructor Characteristics

The relationship between student-teacher interactions and learning outcomes has been well documented in the traditional classroom and distant education (Powers & Rossman, 1985). Of particular importance in traditional classrooms is teacher “immediacy tendencies.” Immediacy alludes to the psychological distance between student and instructor (Weiner & Mehrabian, 1968). Research suggests that a teacher’s verbal and non-verbal immediacy behaviors can lessen the perceived distance between themselves and their students. By lessening the perception of disconnect between the instructor and student in a course, instructors can help facilitate (directly or indirectly) effective learning. Pollard, et. al., (2013) found a significant association between teacher presence and learner motivation in the online environment.

With the importance of interactions established as a crucial component of learning, one might assume it would be equally important online. Certain researchers have suggested that asynchronous media are less capable of representing the social presence of participants (Short, Williams & Christie, 1976). Researchers with experience teaching online contest this view, arguing that rather than being impersonal, computer-mediated communication often seems to be hyper-personal (Walther, 1994). According to Kilburn (2005), research indicates that participants in online courses communicate, argue, and create social presence by projecting immediacy behaviors (LaRose & Whitten, 2000; Garrison & Anderson, 2003; Rourke, Anderson, Garrison & Archer, 2001;). Kizilcec, Bailenson and Gomez (2015) highlighted the benefits of social and other nonverbal cues from the instructor during online video lectures that included the instructor’s “talking head”. This reportedly helped learner’s focus and feel more connected.

Interactions among students seem to clearly matter in online discussions. The development of social presence and the perceived interaction with

others is one of the cornerstones for the development of online communities (Rourke, Anderson, Garrison & Archer, 2001). Lu and Jeng (2006) discovered that instructors who strived to serve as both facilitator and co-participant were helpful in “enhancing knowledge construction,” particularly in discussion forums (p. 196). Students also prefer courses and assignments that included opportunities to apply content and not just reference the textbook (Deggs, Grover, Kacirek, 2010).

Jiang and Ting (2000) report correlations between perceived learning in online courses and the specificity of the instructors’ discussion, instructions and the percent of course grades based on discussion responses. Recent research has found that online graduate students place great importance on the availability of, access to, and feedback from faculty (Fahy, Spencer, & Halinski, 2008). These studies exemplify the magnitude of importance that is placed on the instructor to assure the quality of an online course.

Researchers have begun to look at the changing roles of teachers in online classrooms (Guasch, Alvarez & Espasa, 2010). Coppola, Hiltz and Rotter, (2001) assert that in any environment teachers have three roles – cognitive, affective, and managerial. They found that with online courses the cognitive role often shifts to one of deeper complexity. The affective role requires instructors to find new tools to express emotion and the managerial role requires greater attention to detail, more structure, and additional student monitoring. Easton (2003) reported that prior to the start of class, the instructor role was more like an instructional designer and subject matter expert; however, once the class began, the instructor’s activities took on more of an interactive, facilitator role. Darabi, Sikorski & Harvey (2006) describe the various instructors’ roles as: managerial, social and technical. Mupina, et. al., (2006) reported the top four needs of online students were: technical help, flexible and understanding instructors, early information about the course, and sample assignments. Faculty must also communicate regularly with students through consistent feedback, responses to post-

ings, and responses to concerns (Vesely, Bloom & Sherlock, 2007).

Paul and Cochran (2013) suggest four components are “necessary and important as single entities for delivering and utilizing online education, the larger risks and rewards for online education occur where these components intersect” (p. 50). The four components are institution, student, faculty and technology.

Janicki & Liegle (2001) evaluated the work of a wide range of instructional design professionals and developed a list of ten concepts believed to support effective design of web-based instruction. The findings included: (1) instructors acting as facilitators, (2) usage of a variety of presentation styles, (3) multiple exercises, (4) hands-on problems, (5) learner control of pacing, (6) frequent testing, (7) clear feedback, (8) consistent layout, (9) clear navigation, and (10) available help screens. With the number of online programs and course offerings increasing, faculty roles and the nature of teaching is changing. More faculty and support staff are required to meet the demands of online learning at many institutions (Bennett & Lockyer, 2004; Wiesenbergs & Stacey, 2008). Online teachers “are required to possess a diverse set of competencies and their extent of utilization relies on the context or role they are required to perform and also the kind of resources and support available” (Bawane & Spector, 2009, p. 387). Britt (2015) suggests that allowing students to use real world knowledge is vital for a valuable online classroom experience. Faculty must ensure they are up-to-date with the latest methods to enhance online education.

Interaction has been acknowledged as an important component of learning in conventional and distance education (Moore, 1993). Studies have argued for the importance of instructors’ social or interpersonal feedback when attempting to improve learning achievement in online courses (Jung, 2000). Dennen, Darabie & Smith (2007) have suggested effective online instructors adopt the following practices: (1) maintaining frequency of contact, (2) having a presence in class discussion, and (3) making expectations clear to

learners. Similarly, Hunter (2011) suggests that interaction is a critical expectation that influences student satisfaction. Live chat session, instant messaging options, discussion board participation, course announcements, grading feedback and timely response to e-mails are just a few ways that increased accessibility can be accomplished.

Instructors must balance academic interaction related to the subject matter with more personal student interaction that will cultivate a sense of relationship and community (Moller, 1998). Dennen (2007) purports that “instructors establish a persona via both presence (amount of instructor posts) and position (interaction relative to those in the student role)” (p. 95). Some online learners find it challenging to stay on task. Consequently, they fail to complete coursework. Prompt e-mail responses may help students remain on task and on schedule (Nandi, Hamilton & Harland, 2012). Baran, Correia, and Thompson (2011) suggest that because online students are expected to take control of their learning and become actively involved in the process, facilitation of online learning plays a greater role.

FUTURE RESEARCH DIRECTIONS

As online learning continues to grow in the higher education arena, more research needs to be done on the changing roles of students and instructors in the online environment. Time is no longer spent in the classroom passively listening to a lecture; students are required to play a more active role in their learning. Instructors often struggle to adapt their teaching approaches to develop active interaction and engagement in their online courses.

Rethinking quality assurance, how to measure student success and what constitutes quality interaction will be a crucial step in moving instructors and administrators from the traditional teaching and classroom management frame of reference to the “virtual campus.” Encouraging instructors and students to “think outside the box” and experiment with ways to enhance interaction will help shape the future of online learning.

CONCLUSION

Students will need to adjust to a more self-directed, student-centered approach to learning, while instructors will need to move toward a facilitating model of instruction. Understanding how to assist both students and instructors to adjust to more nontraditional roles in academe is critical. Instructional designers in higher education have the crucial role of helping outstanding face-to-face instructors translate their expertise, knowledge and personality into outstanding online courses. This discussion has reinforced the argument that developing an online course is not a matter of simply putting lecture notes and presentations online. Instructors must assume both an affective and managerial role, going so far as predicting which students may warrant intervention. The instructional designer must help them stock a new “tool box” to effectively transfer knowledge, communicate with their students and develop a sense of community in the online environment. Administrators may also need to rethink how to evaluate instructors in the promotion and tenure process in order to acknowledge instructors who excel in the online environment and make that crucial connection with their students.

Understanding the premises and concepts in this discussion will not only assist administrators and instructors in developing quality online courses and programs, but also provide an understanding of how online learning has resulted in an evolution of student and instructor roles. Successful students take on a more active and participative role and successful instructors take on a more facilitative and supportive role.

KEY TERMS AND DEFINITIONS

Asynchronous Learning: Electronic communication in which the student and teacher interact via e-mail and listservs, but do not do so

by being on the Internet at the same time (Berge & Collins, 1995).

Distance Learning: Learning that occurs when the instructor and students are separated by physical distance and technology is used to bridge the instructional gap (Boaz, Elliott, Foshee, Hardy, Jarmon, & Olcott, 1999).

Online Learning/Course: A context for learning in which students interact using technology and do not meet in a physical classroom with the instructor.

Synchronous Learning: Adjective used to describe an operation performed at the same time as another event (Boaz, et al., 1999).

Web-Based Instruction: A media-rich online environment allowing people to interact with others asynchronously or synchronously in collaborative and distributed environments (Harasim, 1995), to gain access to remote multi-media databases for active and resource-based learning (Jung & Lee, 1993), and to manage self-paced individual learning in a flexible way (Reeves & Reeves, 1997).

Increasing Student Engagement and Participation Through Course Methodology

INTRODUCTION

Educators have been criticized for limited resources in building capacity for continued growth through reflective learning (Demirbulak, 2012). A large number of educational institutions concentrate on acquiring formal knowledge of the subject matter excessively, with theory being overstated and the practical realities of the classroom not being effectively addressed. This is a formidable challenge that educators face and has led to research in trying to develop lifelong learning by being reflective. Reflective education is observing one's own educational practices and thinking about what works and evaluating the approach to see if it is effective or not (Demirbulak, 2012).

Reflection bridges the chasm between theory and practice enabling educators to apply their knowledge for effective learning that is vital for success. This chasm could be the cause of educators avoiding uncertain, possibly rewarding, activities and ignoring cognitive activities (Edwards & Protheroe, 2003). Educators tend to prefer the more traditional teaching methods that are teacher-centered and express anxiety with the perception of student-centered learning (Ozgun-Koca & Sen, 2006). Concurrently, other factors (e.g., poor classroom management, limited knowledge of correlated subjects, insecurity) limit the opportunity for a more rich educational experi-

ence (Demirbulak, 2012). Even with these factors considered, it is the educator's responsibility to design courses that utilize reflective educational practices that are effective (Demirbulak, 2012). Therefore, dynamic educational approaches are necessary and should be integrated in a well-balanced manner. Practices that are learner-focused increase the probability of success by increasing student engagement in the classroom.

According to Günüç and Kuzu (2014a), the increase use of technology is facilitating greater learner participation and is a boon to the academic environment. Günüç and Kuzu posit that it is essential to take technology into consideration in the classroom due to the near universal acceptance of technology into every aspects of life. Digital natives, individuals surnamed because they were born in an era immersed in the technology, see this technology (e.g., iPads, Surface Pros, Smart Phones...etc.) as normal. This particular demographic of learner differ from other generations in this respect (Günüç & Kuzu, 2014a). For the adult learner (historically referred to as non-traditional learner), likes the convenience the technology provides (e.g., access to education and coursework virtually 24 hours a day, from any location). However, all adult learners are not the same, do not learn the same, and desire a more dynamic educational approach. Despite this perspective, a singular approach to the learning process tends

DOI: 10.4018/978-1-5225-2255-3.ch126

to dominate educational practices—lecture. This myopic approach is based on principles, theories, and teaching methodologies that have existed for centuries that do not take into account the diversity and cultural differences of learners. Concomitantly, educators and educational systems are responding to the needs of learners with a combination of educational methodological approaches—pedagogy and andragogy.

Pedagogy uses prescribed subject matter with little room for deviation, it is supported by external motivation factors such as grades to promote engagement and learners are dependent upon the instructor to determine how much and how well they learn (Educational Technology and Mobile Learning, 2015). Andragogy, uses technological tools to enhance learning for adults, encourages self-directedness, and incorporates personal experiences into the learning process (Educational Technology and Mobile Learning, 2015). This chapter investigates the aforementioned methodologies found to be effective for adult learners. The chapter will consist of the following sections: background; issues controversies and problems; solutions and recommendations; future research directions; and the conclusion. The information contained herein will enhance the field of education and course methodology and influence modern educational institutions and society in general.

BACKGROUND

Foundational theorist such Immanuel Kant explored education in, *On Pedagogy* (Über Pädagogik). Here, the image of Greek pedagogues walking alongside their charges, or sitting with them in classrooms, represents the quintessential picture of exemplary education. Eisner (1979, 1985, 1994) argued that the ability to reflect, imagine, and respond involves developing “the ideas, the awareness, the skills, and the mind to create work that is well balanced, adeptly accomplished, and inventive, regardless of the domain in which an individual works ” (this needs a page reference).

Schön’s (1983) work on reflective practice and his critique of the sort of “technical rationality” crudely employed within more “scientific” approaches to practice has been influential (where and/or how?).

This approach to education and thinking is consistent with pedagogues and their ability to reflect, make judgements, and respond (Smith and Smith, 2008). Alegria (2014) found that critical pedagogy literature emphasized the following themes:

- Teaching that focuses on the students ‘culture, socioeconomic status, familial connections, and identity (who are they, identity/personal growth).
- Teaching that emphasizes academic skills and knowledge of the student as well as his or her development of critical thinking (academic/cognitive).
- Teaching that develops students’ critical understanding of society, power, the inequality embedded in activities to make the student ware of their role in society, their understanding of inequality (who is in power and why and their own personal power to change their status or role).

Andragogy was first coined in Europe of 1833 by Alexander Kapp. However, many credit Malcom Knowles with the patriarchal role of the evolution and sculpting of andragogy in the United States (“Culture and process of adult learning”, 2013). Malcolm Knowles, an American practitioner and theorist of adult education, defined andragogy as “the art and science of helping adults learn”. Knowles was convinced that adults and children learned differently. This provided the basis for a distinctive field of investigation. Knowles identified the six principles of adult learning as:

- Adults are internally motivated and self-directed.
- Adults bring life experiences and knowledge to learning experiences.

Table 1. Pedagogy vs. andragogy

	Pedagogical	Anagogical
The Learner	The learner is dependent upon the instructor for all learning. The teacher assumes full responsibility for what is being taught and how it is learned. The teacher evaluates learning.	The learner is self-directed. The learner is responsible for their own learning. Self-evaluation is characteristic of this approach.
Role of the Learner's Experience	The learner comes to the activity with little experience that could be tapped as a resource for learning. The experience of the teacher is most influential.	The learner brings a greater volume and quality of experience. Adults are a rich resource for one another. Different experiences assure diversity in groups of adults. Experience becomes the source of self-identity.
Readiness to Learn	Students are told what they have to learn in order to advance to the next level of mastery.	Any change is likely to trigger a readiness to learn. The need to know in order to perform more effectively in some aspect of one's life is important. Ability to assess gaps between where one is now and where one wants and needs to be.
Orientation to Learning	Learning is a process of acquiring prescribed subject matter. Contents units are sequenced according to the logic of the subject matter.	Learners want to perform task, solve problem, and live in a more satisfying way. Learning must have relevance to real-life tasks. Learning is organized around life and work situations rather than subject matter units.
Motivation for Learning	Primarily motivated by external pressures, competition for grades, and the consequences of failure.	Internal motivators, self-esteem, recognition, better equality of life, self-confidence, and self-actualization.

Retrieved from: Educational Technology and Mobile Learning (2015)

- Adults are goal oriented.
- Adults are relevancy oriented.
- Adults are practical.
- Adult learners like to be respected.

Eminent theorists, such as Paulo Freire, talked about pedagogy in relation to working with adults, there are others such as Knowles (1970) who argue that it cannot escape its roots is bound up with practice with children. Table 1 illuminates the differences between pedagogy and andragogy.

Student engagement symbolizes the time and effort adult learners dedicate to activities that are empirically connected to desired outcomes of educational institutions to induce students to participate in these activities (Kuh, 2009): Table 2 is the foundations of engagement historical growth.

Today's students referred to as learners of the 21st century, learners of the new millennium, generation Y, Internet generation, and technological natives are defined by Prensky (2001) as "digital natives" as they are born into technology use and

technology culture. Many have stated for digital natives, technology is much more than a tool because it is considered a way of life and because technological environments are regarded as an ordinary natural environment.

Table 2. The foundations of engagement historical growth as taken from Kuh (2009)

Name	Authors and Time Frames
Time on Task	(Tyler, 1930s),
Quality of Effort	(Pace, 1982)
Student Involvement	(Astin, 1984).
Social and Academic Integration	(Tinto, 1993).
Good practices in Undergraduate Education	(Chickering & Gamson, 1987)
College Impact	(Pascarella, 1985)
Student Engagement	(Kuh, 2009)

INCREASING STUDENT ENGAGEMENT AND PARTICIPATION THROUGH COURSE METHODOLOGY ISSUES, CONTROVERSIES, PROBLEMS

When educators discuss learning, they use the word pedagogy. At its root, pedagogy refers to “leading children”, this concept can be misleading due to the effectiveness of the approach on undergraduate students. The apparent reference to the science of leading children seems contrary to preparing a learner for an adult world that is evolving technologically (Batson, 2011). There is definite need to understand how adults learn and design the undergraduate experience accordingly. A primary function of critical pedagogy is to critique, expose, and challenge the manner in which education impacts the political and cultural life of students. Educators need to recognize how colleges and universities bond knowledge and power, and how they can work to influence or impede the formation of critically thinking and socially active individuals (Darder, 1995).

Adult learners’ attentiveness, perceptions and willingness are fairly important for academic achievement and attendance. Their engagement helps them benefit efficiently from courses. Krause and Coates (2008) related student engagement to high quality in learning outcomes. Both the learner and the institution, the two sharers of education, are responsible for increasing the level of student engagement (Trowler, 2010). Adult learner engagement is a sociological and psychological concept (Kahu, 2013). Gunuc and Kuzu (2014b) defined student engagement as the quality and quantity of learners’ psychological, cognitive, emotional and behavioral reactions to the learning process in or out of class academic and social activities to achieve successful learning outcomes. The traditional perceptions of education claims to be impartial and apolitical, pedagogy interprets all educational theory as closely linked to ideologies shaped by power, politics, history, and culture (Batson, 2011). Given this view, edu-

cation functions as an environment of continuing struggle over what will be accepted as legitimate knowledge and culture. Pedagogy must earnestly address the concept of cultural politics by legitimizing and challenging cultural experiences that encompass the histories and social realities that in turn comprise the forms and boundaries that give meaning to student lives (Kelly, 2014).

The body of research about learning and pedagogy is evolving. Educators are still of the opinion of not knowing even the rudimentary theoretical terminology to use, to better comprehend the changes and make knowledgeable decisions about changes (Batson, 2011). Clearly, we have moved from knowledge stability and entered a time of extraordinary change, with Web 2.0, a term coined in 2004, is a description of the new Web architecture (Batson, 2011). It is historic marker between the era of contented stability and the era of disconcerting change. Many educators have accordingly turned to learning and away from teaching. Most educators are unaware of the degree of change necessary or the degree to which change will continue over the coming years. Educator in higher education have been searching around the edges of learning research for decades, and have dealt daily with the issues of learning (Batson, 2011). One research thread that seemed to lead to a rich stratum of ideas about learning started with a Google search of the term “situated cognition”. Situated cognition, and related research threads, seems a useful concept for beginning to understand the tendencies of information technology for teaching and learning (Batson, 2011).

Andragogy has produced many scholarly efforts with puzzling empirical investigations. Debates abound over an accurate and consistent definition for “andragogy”. Educator’s definitions range from “adult leader” to “leader of adults” to “learning of adults” which has caused skepticism (“Culture and process of adult learning”, 2013). Over the years, dubious empirical research has existed testing the reliability and validity of the theory of andragogy. Unlike pedagogy, which is known for teacher centered learning; andragogy

has an elasticity of meaning. Perhaps there are essential actions researchers can examine to help validate andragogy's long-standing theory. Rachal (2002) postulates seven criteria to help put the theory of andragogy into perspective:

- **Voluntary Participation:** The andragogy researcher should examine or design learning situations in which the adult learner wants to participate for her own personal fulfillment or some other internal motivator.
- **Adult Status:** Future andragogy studies should avoid college settings if the various groups being compared are partly comprised of traditional college students.
- **Collaboratively-Determined Objectives:** The andragogy researcher should examine or design learning situations in which, the adult learner plays a significant or even primary role in the determination of the learning objectives.
- **Performance-Based Assessment of Achievement:** When the purpose of the analogical learning experience is primarily proficiency or competence in a content area, the andragogy researcher must examine achievement.
- **Measuring Satisfaction:** Many adult education activities do not have as their objective the mastery of some content or acquisition of a skill, but rather the inherent pleasure or satisfaction of participating in a learning activity.
- **Appropriate Adult Learning Environment:** Future andragogy studies should make every attempt to insure that both the physical and the psychological environments are as congruent as possible with Knowlesian guidelines for adult learning settings.
- **Technical Issues:** Ideally, random assignment of participants should occur, but the realities of adult education research are such that in situ groups are the norm and should be considered acceptable (p. 219-224).

to disengage students from learning and create conflict between adult learners and the educational institution (Pedró, 2006).

SOLUTIONS AND RECOMMENDATIONS

In recent years, educators have drawn attention to such problems as low level of student engagement, dropout at early age, poor student behavior, and low level of academic achievement (Harris, 2008). Unfortunately, inflexible, intolerant, or arrogant educators who were successful using each of the approaches, purposefully or inadvertently, created a learning situation where pedagogy and andragogy were siloed; and not considered for the combination possible in a blend of the approaches. However, Strohschen and Elazier (2011) and Peterson and Ray (2013) suggest there is an educational approach that combines the advantages of pedagogy and andragogy to benefit the learner by focusing intensely on the needs of the learner. Educators and adult learners come from two generations, which have two different technological cultures, coming to conflict in a classroom environment. Some adult learners believe that the Internet has an instructional potential than educators (Kolikant, 2009). On the other hand, educators believe students are non-attentive in classes and students are reluctant to learn. Prensky (2001) suggests technology may be the bridge needed to connect the two generational differences. One where educators understand the language of digital natives and use methodological approaches that are considerate of the adult learner, as educational institutions become a central part of adult learners' lives (Kolikant, 2009).

Educators having zeal to educate across the human spectrum must include an understanding of how to maintain educational effectiveness. Scholarly proliferation of educational philosophies, theories, strategies, and approaches produced by the introduction of prefixes attached to agogos, with accompanying academic support, has created learning situations across the anthropological spec-

trum. Pedagogical processes positions learners as having limited knowledge and no life experiences as they relate to the subject matter for the acquisition of knowledge. Andragogical processes positions learners as knowledgeable, responsible, and self-directed. This perspective assumes that adult learners will be more receptive to the learning process and will experience a higher level of engagement than adult learners who are educated using the aforementioned pedagogical approach. By connecting disciplines, in part or entirely, the transdisciplinary educator demonstrates the utility of the information contained in the course in a myriad of life situations that are useful inside and outside of the classroom. This aspect of the educator's learning approach is consistent with the andragogical approach and contains characteristics of pedagogical methodology.

McCaslin and Scott (2012) promoted that metagogy is an independent-interdependent approach to the learning process with the educator functioning as the "potentiator" of the learning process. McCaslin and Scott (2012) suggest that the educator creates the possibility for the acquisition of knowledge, with the adult learner ultimately responsible for learning. In the metagogical approach, the educator switches between pedagogy and andragogy to create a learning environment that compensates for the adult learner's low level of knowledge in an area and promote self-directedness in areas where the adult learner is proficient. In this environment, the transdisciplinary educator is the catalyst for the learning process and depends on the adult learner being intrinsically driven to explore the richness of the learning experience. According to Blaschke, (2012)) heutagogy is defined as the study of

self-determined learning, as a progression from earlier educational methodologies to a point where there is an interdependent learning relationship between the educator and adult learner. The complex, adaptive, and self-determined nature of the adult learner, the environment, and the situation creates a learning situation that can be exciting (Canter, 2012). The heutagogical approach uses intrinsically motivated principles with an understanding that the extrinsic impetus comes from the completing the task at hand Blaschke, (2012).

Pedagogical, andragogical, metagogical, and heutagogical educational approaches to the learning process are individually appropriate and effective for facilitating the engagement of the adult learner. When using these processes to educate adult learners, there are active and passive period of interactions that occur between the adult learner and educator in the course of the acquisition and transfer of information that will constitute learning. Table 3 is an example of the interactions, dependent upon the level of learning; the adult learner will be directed or determined in the education process

In order to select the proper educational approach to facilitate learning for the adult learner, a proper evaluation of the adult learner's level of preparedness has to be identified. Amy Herman, author of *The Art of Perception*, advocates the "Four A's" to evaluate most education and training situations:

1. Assess.
2. Analyze.
3. Articulate.
4. Adapt (Herman, 2015).

Table 3. An example of the interactions taken from DiLullo, C. McGee, P. Kriebel, R. M. (2011)

Type	Adult Learning Orientation	Drivers of Education
Pedagogy	Passive Receiver	Educator Directed
Andragogy	Active Receiver-Passive Transmitter	Educator-Learner Directed
Metagogy	Active Transmitter-Active Receiver	Educator-Learner Determined
Heutagogy	Active Transmitter	Learner Determined

During the assessment phase, the focus is to determine the knowledge, skill, and aptitude of the adult learner. This can be accomplished using any number of procedures (e.g., formative assessment, questionnaire, general conversation, classroom interaction) via any number of methods of delivery (Canter, 2012). Essential to this process is suspending judgment of the information until the analysis phase; therefore, all information is considered. Herman (2015) analytical approach to the educational process is relative to the educator for two reasons:

1. To unpack assumptions.
2. To select an educational approach most beneficial for the adult learner.

In the analysis phase, the information received is critically examined to determine what information is necessary and what information should be discarded. The essential information is segregated and extracted from the non-essential information and weighed against the need(s) of the adult learner to ensure a reasonable degree of certainty that the approach considered is commensurate with needs of the adult learner.

FUTURE RESEARCH DIRECTIONS

In today's global economy, it is necessary for workers and adult learners to have critical thinking skills, creative problems solving abilities, and self-direction to initiate change for improvement in education, workplace practices and life. Self-directedness is essential to workers and learners in the 21st century due to the rapidly proliferation of technology and the changing nature of the workplace. According to Guglielmino (2014), it is nearly impossible for the educational and curriculum designers to remain current on what exactly is required of the adult learners in the classroom without the self-determined nature inherent in the learning processes. Holford and Van der Veen (2003) reported that in European

countries (i.e., Spain, Finland, and Belgium) the desire is to have secondary educators instill adult learners with the ability to think and reason for themselves in order to become a part of growing responsible citizenry. According to Freidman (2005) with more and more companies relying on a "flat" hierarchical arrangement in the workplace, it is imperative that adult learners and workers inculcate a self-directed philosophy if a company is to remain viable in the 21st century.

The information contained in this report supports need for lifelong and advanced learning by workers and adult learners in the 21st century. Livingstone and Rakov (2013) suggest professional and industry workers in Canada depend on certification, recertification, and continuous learning to maintain proficiency and employment. The 21st century adult learners and professionals in growing and emerging fields bring prior knowledge, life and work experience, and expert knowledge to the learning environment that are integral components of advance learning processes (i.e., metagogy and heutagogy). Concurrently, Formosa (2014) writes of the coming of the "third age" learners. These are people are near retirement, retired, or past the age of employment, however they engage in formal and informal education. They actively seek the engagement, companionship, and continued mental growth in educational environments. Through the metagogical and heutagogical approaches broached in the classroom, adult learners have the opportunity to provide critical inquiry and expect resolution and/or inclusion to assuage the concerns on the adult learners and provide effective instruction in the classroom.

CONCLUSION

Clearly, we have moved from knowledge stability and entered a time of extraordinary change, with Web 2.0, a term coined in 2004. It is a historic marker between the era of contented stability and the era of disconcerting change. Many educators

have accordingly turned to learning and away from teaching. Most educators are unaware of the degree of change necessary or the degree to which change will continue over the coming years. In recent years, Educators have drawn attention to such problems as low level of student engagement, dropout at early age, poor student behavior, and low level of academic achievement. Scholarly proliferation of educational philosophies, theories, strategies, and approaches produced by the introduction of prefixes attached to agogos, with accompanying academic support, has created learning situations across the anthrological spectrum. There is a critical need for educational approaches that are adult learner-focused and utilitarian across cultures. Implementing education where adult learners are involved with and have input into the content and execution of the course is appealing in both reason and utility. Through the metagogical and heutagogical approaches broached in the classroom, adult learners have the opportunity to provide critical inquiry and expect resolution and/or inclusion to assuage the concerns on the adult learners and provide effective instruction in the classroom.

KEY TERMS AND DEFINITIONS

Agogos: From the Greek *agein* “to lead” or “leader of.”

Anthropological Spectrum: The process of human learning across a continuum of educational approaches.

Heutagogical Approaches: Educational approaches where the self-directedness of the learning process allows the learner the flexibility to adjust the learning situation to meet the changing nature of the educational or social phenomena.

Metagogical Approaches: Educational approaches that combine the advantages of pedagogy and andragogy to increase the effectiveness of the educational process.

Potentiator: A person that creates learning opportunities.

Siloed: “Silos” are organizations where each department concentrates on their own objectives. The departments are not working for the good or the whole of the organization. An extreme example of this negative impact of what “silos” can do in an organization is when one department sabotages another. For the purpose of this “soloed” is sepa-

rating pedagogy and andragogy and not using the methodology together.

Third Age Learners: People who are near retirement, retired, and/or past the age of employment but engage in formal and informal education.

Transdisciplinary: The framework for allowing members of an educational team to contribute knowledge and skills, collaborate with other members, and collectively create knowledge.

C

Instructional Real World Community Engagement

Caroline M. Crawford

University of Houston – Clear Lake, USA

INTRODUCTION

The imperative needs towards the integration of real world community engagement throughout the instructional process is inherent within the instructional design shifts that are occurring. The Digital Age has introduced the ability to more fully engage the larger community realm within the instructional process, engaging real world professionals, personal relationship engagements and subject matter experts towards supporting the learner's conceptual understandings of the information, cognitive load and self-regulatory concerns of the learner, as well as a recognition that there is a real world connection between learned information and real world implementation of information.

Instructional efforts are important towards developing a knowledge base of subject matter understanding, as well as working with the information in new and different ways so as to further develop a level of knowledge prowess and engage with the information. Yet towards reaching higher order thinking skills (Aini, Nor & Razak, 2015; Anderson & Krathwohl, 2001; Bloom, 1956, 1984; Bloom, Englhart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964; Mishra & Kotecha, 2012, 2016; Ong, Hart & Chen, 2016; Zohar & Barzilai, 2015), it is necessary and appropriate to implement the information in project-focused endeavors. Although traditionally these have been class-based projects or controlled projects for a distinct clientele, the engagement of the learner's understanding within a larger real world community engagement impacts

the learner's levels of personal and professional motivation, enhanced sense of self-efficacy, as well as self-regulatory efforts that reflect not only course-based efforts but also posing within real world community engagement that may include familial, personal and professional communities of engagement. The impact of real world community engagement upon the instructional environment reflects strongly upon learner motivation, external-to-course knowledge checks and analytical feedback, as well as enhancing the positive self-efficacy of the learner internal to and external to the course environment, with the ultimate impact of the instructional experience extending far beyond the requisite course session designations.

BACKGROUND

Discussions surrounding the important elements that impact the instructional environment are worthy of consideration, as the knowledge base within which this real world community engagement occurs is vitally important. The importance and impact of the real world community engagement within the instructional realm is supported by an understanding of cognitive taxonomies, conceptual frameworks of understanding, social discourse, active instructional engagement and implicit cognitive vulnerability that undergirds the holistic understanding of the distinctive importance associated with instructional real world community engagement.

Cognitive Taxonomies

Bloom's Taxonomy of the Cognitive Domain (Aini, Nor & Razak, 2015; Anderson & Krathwohl, 2001; Bloom, 1956, 1984; Bloom, Englhart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964; Mishra & Kotecha, 2012, 2016; Ong, Hart & Chen, 2016; Zohar & Barzilai, 2015) engages in a thought process wherein the instructional process must begin at the knowledge level of learner engagement with the subject matter and then slowly progress through each subsequent level of knowledge engagement and informational understanding (i.e., beginning at the knowledge level, progressing through comprehension, application, analysis, synthesis and evaluation) until the learner has the opportunity to achieve the highest level of the higher order thinking skill capability, specified as the evaluation level of informational engagement. Of interest is Anderson and Krathwohl's (2001) redesigned Taxonomy of the Cognitive Domain for the Digital Age, focusing upon the learner's engagement with the understanding as designated by the lowest level of knowledge engagement (i.e., remember) and then progressing towards the highest level of learner's cognitive engagement with the information (i.e., from remember, and progressing through understand, apply, analyze, evaluate, and create as the highest level of informational engagement and thought process).

The importance of Bloom's Taxonomy, including Anderson and Krathwohl's revised taxonomy, considers the viable considerations revolving around exactly how the learner has the opportunity to work with and to more fully understand the subject matter information through progressively more engaged and analytical aspects of engagement. Towards considering the learner's engagement with this information, it is important to consider the real world implications and intimations, not only how this information may be successfully implemented within the real world environment but also how this new subject matter information begins to fit and frame within a

learner's prior subject matter understandings that also include a learner's conceptual framework of understanding.

Conceptual Frameworks of Understanding

Vygotsky's theoretical delineation of a learner's conceptual framework of understanding (Barwell, 2015; Esteban-Guitart, 2015; Metraux, 2015; Montealegre, 2016; Vygotsky, 1933/1966, 1935, 1981; Wang, 2015) critically frames and supports the understanding that the learner brings forward prior knowledge and understanding of information into any new learning experience. The importance of the learning effort is not only towards understanding the subject matter, but also towards appropriately integrating the new information within prior knowledge and concepts, also referred to as conceptual frameworks of understanding. By integrating the social discourse and knowledge checking efforts, inclusive of real world community engagement, the conceptual frameworks of understanding are more strongly engaged within the learner's informational attainment.

Social Discourse

The importance of social discourse was embraced by Wittgenstein (1961) due to his research that reflected a focused interest upon the importance of social engagement and word choice to describe and reflect the learner's understanding of the subject matter (Burr, 2015; Gorski, 2016; Gupta, 2016; Inwood, 2015; Shotter, 2015). Although subject-specific terminology is vital towards understanding the subject matter and respective field of informational engagement, the social aspects as regards communicating about the subject matter and word choices that more holistically reflect the learner's attainment of subject matter information within a bounded engagement level reflects a learned understanding and effort. With consideration towards real world community engagement, social discourse with individuals within

the real world community is vitally important for the learner, not only towards implementing the terminology appropriately but also towards understanding the social discourse that is appropriate and necessary towards more fully engaging with the subject matter and developing a more fully active understanding as regards how the subject matter more directly impacts the real world environment, no matter whether within the professional community of expertise but also within the social and global community of understanding that is beyond the bounds of the “four walls of the classroom”. This active social discourse within a real world community is supported by the concept of active instructional engagement.

Active Instructional Engagement

Instructional efforts and understandings have shifted over the decades, as new and differentiated learning theories have impacted the instructional process. As well, the introduction of technology within the global community has directly impacted the instructional process through not only instructional technology integration into the physical learning environment, but the introduction of disruptive instructional environments such as blended learning, online learning, mobile learning and flipped classroom conceptions have truly unbound the traditional understanding of the instructional environments. However, actively engaging with the subject matter is understood as being integrally important, reflecting a concept termed active instructional engagement. Within active instructional engagement, tactics that have been highlighted include: Tiered Learning; Responsive Design; Immersive Scenarios; Mixed Media Approach; Micro-learning; and, Gamification.

A tiered learning approach breaks the learning process into conceptually relevant areas of understanding. The initial approach is an audio or a video-based visually engaging understanding of the subject matter; one may consider this to be a focused overview of the subject matter to be

learned, so that the learner can understand the progressive steps towards achieving an understanding of the subject matter. A next step in this approach is textually-framed information that is offered as a detailed understanding and representation of the information to be learned. The third component of the tiered learning approach is the ability to work with the new information, to engage and apply the information within a practice-style effort. The importance is the content, but instead of everything focusing upon the content it is a progressive, cognitively conceptual approach that slowly presents information to the learner and then expects the application of the learned information in new and different ways, such as through higher order thinking skills realms (Aini, Nor & Razak, 2015; Anderson & Krathwohl, 2001; Bloom, 1956, 1984; Bloom, Englhart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964; Mishra & Kotecha, 2012, 2016; Ong, Hart & Chen, 2016; Zohar & Barzilai, 2015).

Responsive design is an instructional approach that is embraced within the digital age approach to computer mediated learning efforts. This is due to the ability of the technology-interface environment to slowly progress in a breadth and depth of understanding and engagement with the subject matter, normally increasing access to the information based upon the decision of the learner. As well, the learner also chooses when to engage with the information within a more expansive environmental community.

Immersive scenarios support the learner’s progressive engagement with the subject matter that is normally a process-oriented approach or may engage in an understanding of soft skills subject matter, with the primary approach being that multiple branching choice structures systematize one’s subject-based understandings of learner choices within the immersive scenario offering a progressively responsive learning path towards a designated outcome. As such, instead of supporting the learner’s understanding of information in a behaviorally laden process-oriented step-by-step

approach, the immersive scenarios more fully engage the learner in the progressive decision making process and resulting outcomes of decisions made by the learner. Such immersive scenarios are more focused upon higher order thinking skill choices such as analysis, evaluation, synthesis and creativity, as a learner's social engagement and conceptual frameworks of understanding support not only the understanding of learned subject matter but also the external, real world implications associated with choices that impact the immersive scenario outcomes.

A mixed media approach suggests an active instructional engagement, wherein an overarching theme is implemented throughout the instructional environment, but a differentiated approach is brought forward to support and reflect that theme for the learner. What this suggests is that graphics, audio, video, simulations, animations and innumerable modeling efforts reflect the learning efforts thematic support that is meant to more fully support the learner's conceptual framework of understanding and implicit memory attainment as regards the subject matter under study. As suggested within a mixed media approach's focus upon overarching themes, a semiotic approach is inherent within this framework. A semiotic approach is the study and understanding of meaning-making within a humanist perspective; the study and understanding of meaningful communication and the processes understood by signs and symbols is inherent within this semiotic approach (Chandler, 2014; Chang, 2007; Semiotic Society of America, n.d.; Streeter, 2012a, 2012b).

Micro-learning is the concept of learning modules, within cognitively aware and relevant short modules of subject matter understanding. This concept is also supported by the tiered learning approach, wherein a progressive understanding of the subject matter must be realized so as to ensure that the learner's cognitive conceptualization is supported in a progressively engaged and cognitively sensitive understanding revolving around higher order thinking skills understanding.

Finally, the gamification of information is an effort that has been embraced by instructional technologists. Even as the recognition of gamification has heightened and then waned over the years, the progression from cardboard-based floor games towards cognitively structured pseudo-simulation environments that have become significantly easier to develop within recent years, has again risen the concept of gamification within the distributed learning environments (electronic learning, or elearning) and mobile learning environments. Much as with the conception of Massive Open Online Courses (MOOCs) the short-term behavioral rewards system concept of coins, badges, medals and short term rewards structures that are conceptualized as meaningful for different learner personalities have also been impacting gamification efforts.

Active instructional engagement is really framed as different ways through which to implement instructional efforts, towards reaching different types and personalities of learners. Within bounds, each of these instructional efforts is relevant and worthy of consideration. Towards considering the learner within this effort, the subject matter information may be more fully tested and understood within a real world community environment.

REAL WORLD COMMUNITY ENGAGEMENT

The ultimate effort associated with the learning process, including subject matter information attainment and understanding, is towards not only learning for the love of learning nor towards a more well-rounded citizenry, but in fact the ability to understand the subject matter within the real world community environment is an ultimate understanding and desire to successfully reach this level of subject matter understanding and attainment by each learner engaged in the instructional process. The ability to implement new information within a

grounded real world environment is important, not only towards more fully understanding the learned information but also towards more fully recognizing the worth and impact of the subject matter within a real world community engagement. For this reason, discussions revolving around learner-focused considerations of real world community engagement, knowledge checks occurring within real world community engagement, and types of real world community engagement are offered.

Learner-Focused Considerations

Real world community engagement is vitally important within the learning process for several different reasons. First is the concept of personal and professional motivation, wherein a recognition that learners may engage differently with the learning process and deeply engaging with the subject matter when motivational considerations (Maslow, 1977, 1986, 1997), including Vroom's expectancy theory (1964; Chen, Ellis, Suresh, 2016; Holdford & Lovelace-Elmore, 2001; Hung, Zhuang, & Lin, 2015; Lazaroiu, 2015; Parsons & Geoff, 1978; Purvis, Zagenczyk, & McCray, 2015; Shweiki, Martin, Beekley, Jenoff, Koenig, Kaulback, Lindenbaum, Patel, Rosen, Weinstein, Zubair, & Cohen, 2015; Whittington, 2015) are imbedded. The learner's motivational levels are also inherently important towards a learner's sense of self-efficacy (Bandura, 1977, 1986, 1997), wherein the learner's ability to recognize their own abilities and potentials towards success support the learner's efforts in working with the information, especially in a real world community environment that embraces the opportunity to understand the subject matter within daily usage in new and different manners of understanding. Also of interest is Bandura's (1991) discussion of the impact regarding social cognitive theory upon self-regulation. Conceptually, Bandura suggests that the learner self-influences their success through the ability of a person to self-monitor one's efforts and associated impacts, the ability of a person to judge their behaviors within the bounds of the

environment and associated standards of expectation, as well as the learner's ability to understand the affective influence, or emotional self-reaction within different situations. Primarily, the learner's ability to understand their own actions and reactions within any style of knowledge attainment and information expansion environments is viable and significantly important towards the learner's ability to successfully engage and more fully embrace opportunities towards working with the subject matter information in new and real world community efforts of engagement.

Knowledge Checks

The real world community engagement is a perfect opportunity for a learner to check their understanding of the knowledge under study, as well as more fully engage with the subject matter information in new and different ways that will more fully develop an understanding and "fill in the cognitive blanks" for the learner. This holistic understanding of the subject matter is vitally important, towards progressing out of lower order thinking skills and engaging in higher order thinking skill efforts. Much as what was described in the tiered learning effort, the progressive efforts associated with framing a tiered approach that begins with a controlled understanding of the information, such as in-course knowledge attainment efforts, then shifts towards working with the information in practice and application efforts, with a shift towards external-to-course real world understandings of the subject matter. This real world community engagement offers knowledge checks and analytical feedback efforts that offer the opportunity to critically analyze and correct any conceptual framework of understanding misalignments that are more readily addressed within a real world environment. Engaging the learners within reflective understandings of the subject matter information within the real world community engagement opportunities supports a learner's ability to critically reflect upon why the shift from classroom knowledge attainment and

skills application and practical application within a controlled environment might be differentiated from a real world community engagement with the subject matter is considered vitally important; the analysis and re-learning understandings more fully engage the learner in their own cognitive framing of understanding, as well as a learner's recognition associated with their own self-efficacy (Bandura, 1977, 1986, 1997; Chen, Ellis, Suresh, 2016; Holdford & Lovelace-Elmore, 2001; Hung, Zhuang, & Lin, 2015; Lazaroiu, 2015; Parsons & Geoff, 1978; Purvis, Zagenczyk, & McCray, 2015; Shweiki, Martin, Beekley, Jenoff, Koenig, Kaulback, Lindenbaum, Patel, Rosen, Weinstein, Zubair, & Cohen, 2015; Vroom, 1964; Whittington, 2015), meaning that the learner recognizes the ability to learn and re-learn information within differentiated contexts while still recognizing the learner's ability to successfully overcome and achieve quality levels of knowledge acquisition, subject matter information implementation and successfully reframing conceptual frameworks of understanding.

Types of Real World Community Engagement

Within an instructional environment, there are innumerable ways through which real world community engagement can be successfully addressed and implemented. Much as within a tiered approach towards learning, a tiered approach towards instructional real world community engagement is realized within an instructionally impactful environment. Within an instructional environment, real world community engagement may fall within three distinct constructs: Academic Communities of Engagement; Personal Communities of Engagement; and, Professional Communities of Engagement. Within a tiered community approach, the primary community may be considered the academic community of engagement, the secondary community may be considered the personal communities of engagement, and the tertiary (although by no means lesser

in importance) community may be considered the professional communities of engagement.

Academic Communities of Engagement

Academic communities of engagement revolve around the conception of co-learners and collegial instructors who are all engaged within an academic effort. This focus is towards not only fulfilling their own academic impetus towards learning but also within a collegial effort that engages within a group or communal ability to work with subject matter in new and different ways.

First may be considered the current course colleagues, who are currently engaged in the same course in which the subject matter is under focused consideration. Each course is focused upon its own subject matter focus, as reflected through instructional goals and instructional objectives; for this reason, current course colleagues are all focused upon successfully attaining specific instructional goals and objectives within the designated course environment.

From a differentiated approach, prior course collegial support systems are in place, based upon collegial learner relationships that have been developed and maintained even after a designated course's instructional experience concludes. These learner colleagues may follow different paths towards their own ultimate academic success, but their bounded approach towards academic pursuits and falling within a specific community environment continues to frame prior course collegial support systems as inherently viable support systems. Not only do the prior course collegial support system members understand the culture and associated quality efforts towards attaining academic success, but prior experiences offer a binding motivational support system within which members find collegial and relational support through recognized successes, adventures, and difficulties.

Current and prior instructors also fall within academic communities of engagement, as mentor-apprentice and professional relationships within

the academic community and academic culture naturally arise. The ability of the learners to develop professional relationships with current and prior instructors is integrally important, not only towards the learner's motivational levels and sense of self-efficacy, but also towards engaging with the subject matter in new and different ways; this is true no matter whether the learner engages with the subject matter within a current instructor's course and desires a deeper analytical approach towards understanding the subject matter, or if the learner desires to work with prior instructors towards engaging in a deeper analytical approach and perhaps a differentiated discussion revolving around the subject matter taught within more current coursework so as to analyze and engage with the subject matter in new and different manners that may not be comfortable nor acknowledged by the current instructor.

The academic community of engagement is a viable community environment due to its primary initial level of importance within a learning process as framed through a traditional view of the learning process.

Personal Communities of Engagement

Personal communities of engagement revolve around the conception of social communities of influence who may not have similar understandings of the subject matter under study within the academic community realm. Such a community supports the learner's self-efficacy and self-regulatory efforts that directly revolve around focused efforts and a desire towards successful engagement in a progressive manner. Within the personal community of engagement, one may specify at least three groups of impact: Friends; Family; and, Social Connections.

Friends are an integrally important real world community of impact upon the learner. The learner has a developed relationship with friends, who have a direct impact upon the learner's cognitive stresses and cognitive load concerns, suggesting that friends hold a prestigious level of support and

impact within a learner's ability to learn, engage and reflect upon the subject matter learned within their prior academic community structure. Within a personal community construct, the learner must feel a sense of accomplishment and quality of attainment, to retain information as well as to sustain their level of cognitive engagement in the learning process.

Family have deep-seated roots that are emotional and bonding in nature, and which also mirror the learner's family-specific labels of success or perhaps detrimental underpinnings. The learner's strong sense of support and self-efficacy may begin within the bounds of the family structure. As a family structure, this personal community of engagement bounds the perceptions of the learner by other's opinions of her/himself as a successful learner, as an intelligent person, as well as engaging in motivational behaviors towards the learner's own successes. The support of a family structure is vitally important towards supporting the learner's underlying self-esteem, self-efficacy and motivational efforts. From a more negative point of view, the learner must reflect upon and cognitively engage in a holistic understanding of their familial community of engagement, so as to recognize and potentially rectify any potential concerns that may result in the learner's blocking of successful attainment of their instructional successes that also include working with the subject matter within their personal communities of engagement.

Personal communities of engagement also include social connections. The types of personal social connections that impact a person on a daily basis directly impact the learner's ability to engage in intellectual and holistically emotive and supporting levels of real world community engagement, that may more fully support the learner's ability to recognize their own skill sets and cognitive strengths that result in social successes and analytical empathetic understandings revolving around different viewpoints associated with subject matter from a cultural and social level of community engagement.

The personal community of engagement is a viable community environment due to its secondary level of importance within a learning process as framed through a cognitive constructivist view of the learning process. The personal, cultural and social impact upon a learner's understanding of the subject matter directly impacts the learner's understanding of the subject matter within a real world community engagement scenario.

Professional Communities of Engagement

Professional communities of engagement revolve around the conception of professional communities of influence who may have differentiated backgrounds of subject matter expertise and understanding, yet the ability to engage with the subject matter within a mentor-apprentice relational understanding strengthens the learner's ability to cognitively structure an understanding of the subject matter beyond the realms of academic learning and personal community influence, towards a real world professional community engagement more fully reflects opportunities towards higher order thinking skills efforts and informational attainment. Within the professional community of engagement, one may specify at least three groups of impact: Current Work Colleagues; Prior Work Collegial Support System; and, Professional Organization Colleagues.

Current work colleagues may be considered the first of three levels of professional communities of engagement. Within this community structure, the learner has the opportunity to fully implement the subject matter information with colleagues who may be equally informed as pertains to the depth and breadth of information that the learner brings forward within a professional community environment. Conceptual frameworks of understanding are integrally important within this community structure, as the ability to offer professionally ap-

propriate checks and balances towards supporting the learner's engagement with the subject matter information is vitally important. From a negative viewpoint, unknowledgeable, uninformed or uncomfortably critical colleagues may irreparably damage the learner without the additional mirroring of acceptability by others from within each of the other real world communities of engagement.

Prior work collegial support systems are integrally important towards a learner's successful integration and implementation of the subject matter within the professional environment. This is not only due to the ability of prior work colleagues to dissuade the learner's beliefs and labels as bound by uninformed or ignorant current work colleague critical actions, but also towards developing differentiated understandings about the learned subject matter information in new and different ways, that are beyond the potential bounds of a current work site effort and into a more holistic understanding of the professional communities of engagement. This reflects not only upon the importance and impact of the subject matter information, but may also further engage and reflect upon the learner's conceptual framework of understanding in an extension of engagement and perception beyond prior bounds of comprehension.

The final of the three professional communities of engagement is defined as the professional organization colleagues. These subject matter professionals offer differentiated levels of expertise with the subject matter information with which the learner is working, laboring and toiling. These professional organization colleagues offer an inherent interest in expanding their own professional understandings as revolves around the subject matter, as well as learning new information. This dynamic style of relational real world community engagement is not only a mentor-apprentice relationship but may shift between a more collegial view of subject matter engagement, questioning and analytical creativity.

SOLUTIONS AND RECOMMENDATIONS

Instructional real world community engagement is an integrally important aspect within any instructional process. Within a tiered learning approach, not only must the subject matter be offered in a carefully framed presentation and cognitively discrete understanding of the learner, but the real world community engagement of the learner must also be understood. This real world community engagement of the learner does offer a direct instructional impact upon the learner's cognitive understanding of the subject matter, conceptual framework of understanding, as well as motivation, self-efficacy and fully engaged understanding of the subject matter within a holistic understanding of the subject matter's real world implementation.

FUTURE RESEARCH DIRECTIONS

More fully framing the developing understandings revolving around the real world community engagement's impact upon the instructional process must be more fully realized within academic pursuits. Not only is the real world engagement with the subject matter inherently vital towards the learner's understanding of the information, but recognizing and reflecting upon the differentiated real world community understandings of the subject matter may develop the learners into more reflective practitioners and professional citizenry.

CONCLUSION

Instructional real world community engagement is vitally integral and important towards structuring a knowledge base of subject matter understanding, while also recognizing the working knowledge impact upon the learners. Through an understanding of the theoretical undergirdings as well as a recognition of the real world community engage-

ment components more fully frame the impact of real world community engagement upon the instructional process.

KEY TERMS AND DEFINITIONS

Academic Community: This type of learner-realized real world community engagement falls within three realms of influence, specifically current course colleagues, prior course collegial support system, and current and prior instructors.

Community: This group of people are influential members of a cultural or social environment that may be geographic, emotional or impactful in some important manner of influence. Within this discussion, the community are a group of persons who impact a learner's sense of self as well as sense of subject matter understanding.

Personal Community: This type of learner-realized real world community engagement falls within three realms of influence, specifically friends, family, and social connections.

Professional Community: This type of learner-realized real world community engagement falls

within three realms of influence, specifically current work colleagues, prior work collegial support system, and professional organization colleagues.

Self-Efficacy: This term refers to a learner's ability to identify and distinguish one's own potential towards success. Within this discussion, the term refers to the learner's ability to identify and distinguish one's own potential towards learning success.

Self-Regulation: This is the learner's ability to understand one's own affective actions and reactions, recognize and control one's own environmental conditions, as well as observe one's own conduct and reactive performance.

Tiered Learning: Tiered learning is an instructional design approach. Within the concept of an instructional real world community, the academic, personal and professional communities are tiered engagements.

Learner Engagement in Blended Learning

BACKGROUND

Definitions of Blended Learning

Use of the term *blended learning* remains relatively new in higher education, K-12, and corporate settings. While this is the most commonly used label, the construct is sometimes described with the terms *mixed mode* and *hybrid learning* (Moskal, Dziuban, & Hartman 2013; Picciano, 2014b). Due to the flexible nature of blended learning, the debate continues over a precise definition of the term (Picciano, 2014b). While some consider this ambiguity a weakness that prohibits blended learning from use as a discriminating label (Oliver and Trigwell, 2005), others submit that a more narrow definition would impede “great potentials of the concept” (Alammary, Sherad, & Carbone, p. 443, 2015).

The most widely accepted basic position is that effective BL environments are a combination of F2F learning with technology-mediated instruction (Graham, 2006, 2013). Many individuals and institutions build upon this broad definition include caveats about seat time (Mayadas & Picciano, 2007), and the quality of the blend (Garrison & Kanuka, 2004) or quantity of instruction placed online (Allen & Seaman, 2007). Most current definitions of BL focus on the physical dimensions of the blend (e.g., online and face-to-face). However, future definitions may emphasize more

of the psychological/pedagogical dimensions of the blend (Graham, Henrie, & Gibbons, 2014).

Across contexts and institutions, varying ideas exist of what constitutes a BL environment (Porter, Graham, Spring & Welch, 2014). This distinction is most noticeable between postsecondary and K-12 sectors. Although BL at both levels is similar in many ways, it must be adapted to fit the K-12 setting (Staker & Horn, 2014). Horn & Staker’s (2015) three-part definition of BL focuses on the element of student control over their own learning experience, learning in a supervised brick-and-mortar location away from home, and the importance of an integrated learning experience. The integration aspect focuses on the coherence between the F2F and online components to deliver cohesive instruction for the learner about a given topic (Horn & Staker, 2015). An effective implementation of blended learning is well-coordinated with each component supporting the other.

Despite disagreement on an exact definition, many institutions are adapting BL to suit their specific needs. In each case, institutional context plays an important role in the construction of an operational definition and strategy (Moskal, Dziuban, & Hartman, 2013). The loose definition is “plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites” and thus allows the creation and implementation of customized institutional blends (Star & Griesemer, 1989, p. 393)

Reasons for Blending

A blended approach offers many advantages for both instructors and students. Stein & Graham (2014), Moloney et. al (2011), and Poon (2013) found that these benefits closely align with the Sloan-C Five Pillars of Quality:

1. Improved learning outcomes (including potential for learning communities and collaboration/active learning)
2. Cost reduction and effective use of resources
3. Access and flexibility
4. Student satisfaction
5. Faculty satisfaction

Reduced seat time, flexibility in time and space, and maintaining F2F interaction are some of the advantages of a blended approach (Moskal, Dziuban, & Hartman, 2013). Many educators choose to adopt a blended approach to avoid sacrificing benefits of one method for benefits of the other (e.g. convenience of an asynchronous distributed environment without eliminating the benefit of human contact in the F2F environment). While BL can provide the “best of both worlds” (Bonk & Graham, 2012; Moskal, Dziuban, & Hartman, 2013), if not designed with thoughtful consideration of the combined methods, content, and intended learners’ needs, BL environments can also mix the least effective elements of F2F and online instruction. Thus clearly articulated models are needed to help guide practice and research (Graham, Henrie & Gibbons, 2014; Halverson, Graham, Spring, Drysdale & Henrie, 2014).

LEARNER ENGAGEMENT IN BLENDED LEARNING

Learner engagement has been heavily researched (Azevedo, 2015) and termed the “holy grail” of learning (Sinatra, Heddy & Lombardy, 2015). Engagement is strongly connected to a variety of benefits (Carini, Kuh & Klein, 2006; Mountford-

Zimdars, Sabri, Moore, Sanders, Jones & Higham, 2015). Some positive student outcomes linked to learner engagement include student performance (Casuso-Holgado et al., 2013; Kuh et al., 2008), persistence and resilience (Kuh et al., 2008), and psychological growth (Harper & Quaye, 2009).

Defining Learner Engagement

The educational field has yet to agree upon a standard definition of engagement (Sinatra, Heddy & Lombardy, 2015). Possible competing and/or overlapping definitions span integrating learning strategies and motivations (Richardson & Newby, 2006), a combination of motivation and cognition (Järvelä, Veermanis & Leinonen, 2008), and “emotionally positive” and “cognitively focused” (Skinner and Pitzer, 2012). We suggest that engagement may be conceptualized as the “quality and quantity” of energy exerted (Henrie, Bodily, Manwaring, & Graham, 2015).

The student experience is different in an on-line setting than in a traditional one, and blended engagement presents unique challenge and opportunity for engagement. While the research has not clearly identified the underlying causes for improved outcomes in blended contexts (Means et al., 2013) Blended learning has been identified a means for increasing student engagement (Graham & Robison, 2007; Northey, Bucic, Chylinski, Govind, 2015). More research is needed on the types of blends that produce “deep and meaningful learning” (Bernard, Borokhovski, Schmid, Tamim & Abrami, 2014, p. 116).

Models of Learner Engagement

There are several models that researchers have used to conceptualize engagement. One prominent model characterizes engagement as part of three domains: behavioral, emotional, and cognitive (Fredricks, Blumenfeld, & Paris, 2004). Behavioral engagement is connected to a student’s actions and participation, emotional engagement is related to a student’s feelings about the learning

experience, and cognitive engagement focuses on investment and exerting effort to understand material. This model looks at engagement as a meta-construct which combines multiple aspects of the student experience (Fredricks, Blumenfeld, & Paris, 2004).

Skinner & Pitzer (2012) extended behavioral, emotional, and cognitive engagement to contextual levels with specific outcomes at each. The most expansive is engagement with prosocial *institutions*, like churches and clubs, which produces generally positive development. Second engagement is more limited within a *school* context, including classes and extracurricular activities, which encourage students to remain in school and graduate. Next comes engagement with a *class*, including the instructor, material, and other students, which bolsters student achievement. Finally students can engage in specific *learning activities* which develop academic assets like learning, coping and resilience (Skinner & Pitzer, 2012). This model is useful for identifying the levels at which engagement is measured and conceptualized (Henrie, Halverson & Graham, 2015).

Researchers continue to develop and test new models for measuring engagement in order to track engagement in technology-mediated and blended contexts. Lam et al. (2014) developed a scale to measure cognitive, behavioral, and affective engagement internationally and tested it with over

3,000 students in 12 countries; they found that the scale is valid and can be applied further to student engagement elsewhere in the world. Henrie, Halverson & Graham (2015) identified and analyzed existing methods of measuring engagement, in order to suggest potential improvements in engagement measurement. Henrie, Bodily, Manwaring & Graham (2015) used longitudinal data to study engagement in a blended course and discovered that clear instruction and relevant activities had a greater effect on student engagement than the instructional medium (Figure 1).

Measuring Learning Engagement

Measuring Engagement is a complicated but important task. Gaging learner engagement is difficult because it is challenging to define the construct, to select the granularity at which to measure the engagement, and to avoid disrupting learning while collecting data in real-time (Sinatra, Heddy & Lombardy, 2015).

Granularity, the “size” of engagement, must be addressed. Researchers should carefully examine the theory, definition and grain size of possible measures while planning a study of engagement. Engagement ranges from the micro level (i.e. individual students for short periods of time) to macro level (i.e. many students for sustained periods of time) and measurement methods should correspond

Figure 1. Model of learner engagement

to the engagement level to be measured (Sinatra, Heddy & Lombardy, 2015). Methods for collecting data to measure engagement span the classic self-report (Greene, 2015) to the highly technical eye-tracking (Miller, 2015). Each measurement method has its place, dependent upon fit for theoretical underpinnings and research goals (Fredricks & McColskey, 2012), though some methods are only possible in a blended or online context.

Self-reporting and similar types of data collection might interrupt engagement. (Baker et. al, 2012). Signaling students to respond right away after an event, several times during a learning experience can provide a more complete understanding of their engagement (Järvelä, Veermans, & Leinonen, 2008). However, the more interruptions a student experiences, the more invasive the disruptions may be. Computer-generated information in an online or blended context can be harnessed to allow researchers to collect data in real time without such disruptions (D'Mello & Graesser, 2012; Graesser, D'Mello, & Strain, 2014; Henrie, Halverson & Graham, 2015). It may be possible to infer student engagement from a student's interaction with an online interface with no to minimal disruption to the student's learning experience (Gobert, Baker & Wixton, 2015).

The possibilities for real-time, actionable measures are greatly enhanced by technology. Face and gesture recognition programs allow researchers to gauge someone's emotions based on their facial and upper body expressions (Baltrušaitis et al., 2011). This type of data has been applied to educational contexts (D'Mello & Kory, 2015). Data automatically collected by a learning management system (LMS) can also help determine a student's engagement level. Information about the number of times a student participates in a discussion, sends mail, or completes an assessment can help an instructor understand his students engagement levels (Macfayden & Dawson, 2010; Vivekananthamoorthy & Naganathan, 2015). Harnessing an LMS to monitor student engagement can also help a professor provide timely, meaningful feedback to struggling students.

Learner Engagement in Online and Blended Learning

In a traditional learning environment, students interact face-to-face with instructors in a classroom setting. A typical approach in this context, especially at the postsecondary level, is instruction provided through lecture (Smith & Cardaciotto, 2011). This approach is particularly efficient when dealing with large class sizes, however, a major concern is that of student engagement (Blood & Neel, 2008). It is easier for students to become disengaged in a larger class as there is less personalized instruction and fewer opportunities to actively participate. Generally, students have a more passive role in a traditional setting with instruction being more "educator-focused" (Northey, Bucic, Chylinski & Govind, 2015, p. 171). When opportunities to participation do arise, students indicate their willingness to do so by raising their hand (Barr, 2013). Although some students feel comfortable participating in this manner, others may find this response method intimidating, lessening their desire to contribute to the classroom discussion (Barr, 2013). Problem-based learning and student response systems have been used as methods to increase student engagement in a traditional classroom setting. Studies show these approaches can increase engagement and participation in the traditional context, allowing students to have a more active role (Barr, 2013; Blood & Neel, 2008).

Online learning environments allow students the flexibility and autonomy to control their own learning experience (McBrien, Jones, & Cheng, 2009; Robinson & Hullinger, 2008). As the internet has increased in accessibility so has the number of students opting for online courses (Allen & Seaman, 2008). Robinson & Hullinger (2008) found that higher levels of engagement were reported by online students compared to on-campus students for each of their benchmarks used to measure engagement. The four benchmarks were level of academic challenge, student-faculty interaction, active and collaborative learning,

and enriching educational experience. While the F2F element is not present in online instruction, students are expected to work together, fostering collaboration among participants (Chen, Lambert, & Guidry, 2010). The use of synchronous conference technologies provide opportunities for social interaction in a typically asynchronous environment (McBrien, Jones, & Cheng, 2009). According to Chen, Lambert, & Guidry (2010), students who actively participate in Web-based learning are more likely to make use of practices such as reflective learning, higher order thinking, and integrative learning.

Blended environments allow instructors to harness the capacities of both traditional and online engagement strategies, as well as unique combinations of the two. Complementing face-to-face activities with out-of-class, asynchronous learning opportunities allows educators to create a community-focused space for personalized learning experiences for students (Northey, Bucic, Chylinski, & Govind, 2015). Both environments support each other and offer opportunities for learners to be co-creators of their knowledge. Northey, Bucic, Chylinski & Govind (2015) found that adding an asynchronous component to a course, in the form of social media, improved student engagement and final grades. Their study also found that the positive interactions students experienced through the online portion of a blended course had a positive spillover effect in the F2F setting.

Even within the context of blended learning environments, the method in which the F2F component is delivered can affect the level of engagement. Delialioğlu (2012) found that students reported higher levels of engagement in a problem-based learning environment as opposed to the traditional lecture-based method of delivery. Regardless of the difference between these methods, students were highly satisfied with the blended learning configuration of the course (Delialioğlu, 2012). Although technology plays an integral role in the lives of students, learning how to effectively

leverage this tool in meaningful and engaging ways academically is a task for instructors and students alike (Dahlstrom & Bichsel, 2014).

Interaction is one way to understand how engagement and technology are connected. Moore (1989) divided interaction in distance education into three domains: learner-content, learner-instructor, and learner-learner. In a meta-analysis of experimental literature on interaction in distance education Bernard et al. (2009) found all three types of interaction to positively influence student learning, possibly due to increased cognitive engagement. Interaction should be mindfully included in courses and activities designed to promote engagement (Meyer, 2014). These types of interaction in online and blended learning can also be understood as human-technology interaction (i.e. learner-content interaction) and human-human interaction (i.e. learner-instructor and learner-learner interaction).

Strong learner-content interaction can improve learner outcomes. Zimmerman (2012) found that learners who spent more time interacting with content earned higher grades in a course. Creating meaningful interactions with content, rather than simply providing it, also improves student outcomes (Dunlap, Sobel & Sands, 2007). Hillman, Willis, & Gunawardena (1994) extended interaction to a fourth domain, learner-interface interaction and argued that specific strategies should be applied to this type of learning experience. We would conceptualize both learner-content and learner-interface interaction as human-technology interaction in an online or blended context. There are obvious differences between a static book, or even an e-book or eLearning course and a the dynamic possibilities provided by modern technology in terms of interaction as well as data collection. Automated engagement detection programs, which track a student's engagement individually, in real time, have success rates that are comparable to those of human raters (Whitehill, Serpell, Lin, Foster & Movellan, 2014). Interventions are even being tested to respond to

students apparent emotions with appropriate facial expression from a computer generated model (Jayareka & Rajamohamed, 2015).

Students may also engage differently when they are experiencing learner-human interaction as opposed to learner-content or learning-technology interaction. A plethora of technologies are available to foster human-human interaction in online and blended contexts both synchronously and asynchronously. Blogs, wikis, video conferencing, live presentation tools, emails, chats, and many other emerging technologies are versatile ways to include human-human interaction at a distance (Beldarrain, 2006). While there was variation between types of interactions, Borokhovski, Tamim, Bernard & Abrami et al. (2012) found that contextual interactions which provided an environment for student interaction but were not purposefully created to promote collaboration were less effective than designed interactions which were more beneficial to student achievement. Learner-instructor interaction is also an important dimension of human-human interaction. Shackelford & Maxwell (2012) found instructor modeling, encouragement and other facets of learner-instructor interaction cultivated a greater sense of community for students.

FUTURE RESEARCH DIRECTIONS IN ENGAGEMENT IN ONLINE AND BLENDED CONTEXTS

In 2006 Bonk, Kim, and Zeng (p. 560) made some predictions about the future of blended learning:

1. Increased use of mobile devices in BL
2. Greater use of visualization tools and hands-on learning
3. Increased learner input in designing their own learning programs
4. Increased connectedness, community, and collaboration
5. Increased authenticity and on-demand learning
6. Stronger ties between work and learning
7. More flexible calendaring system
8. More inclusion of BL course designations in program descriptions
9. Increased movement in instructor roles toward mentoring, coaching, and counseling

Some of these predictions are manifest in the succeeding literature as developing trends. Models such as the self (à la carte) blend, buffet blend, or field blend give students more input in designing their own learning. Additionally, formats like the flex model, rotation model, the emporium and fully online blends are beginning to shift the role of the instructor. The literature has mentioned increased connectedness, community, and collaboration (see Poon, 2013). However, for some of the other predictions it may be too early to know whether they truly become trends.

While the future of BL environments is hard to predict, the use of BL in K-12, higher education, and corporate contexts will likely continue to increase and may become the norm as predicted. Future learning environments may be predominantly BL, and the adjective *blended* may no longer be needed. Focus in higher education may be on whether blending is happening or not, and universities may be more concerned with the quality of the blend and seek to understand how faculty can be trained and supported to teach in BL environments. Some related trends might develop:

1. Increasing use of learning analytics to help improve learning (online and blended models allow for easier data collection; see Picciano, 2014b). A better understanding of student engagement and more advanced mechanisms for measuring, responding to, and supporting student engagement in real-time.
2. Increasing personalization of learning (see Horn et al., 2011), especially in response to individual student engagement data.
3. Movement of instructor roles toward mentoring, coaching, and counseling as learner-content or human-technology interaction

can be made more engaging for information delivery and human-human interaction can focus on the personal aspects of learner.

Corporate and military contexts are most likely to continue to push the technological envelope, exploring more expensive technologies, although simulations may be used more commonly in K-12 and higher education classrooms.

CONCLUSION

Because access to and understanding of technology are spreading, we see unprecedented availability of instructional resources and efficient communication. However online and F2F learning environments have unique benefits. Because of varied strengths, the present move toward blending online and F2F instruction has valuable potential that warrants further consideration and research. Blended learning has much potential for improving both student engagement and the ability for researchers and instructors to measure and develop that engagement. Researchers must continue to work toward a consistent definition and validated models of learner engagement. We feel that in this endeavor researchers and practitioners will be able to enhance blending strategies to accomplish the objectives for which BL efforts are initiated.

KEY TERMS AND DEFINITIONS

Blended Learning Environment: A learning environment that combines face-to-face and computer-mediated instruction.

Cognitive Engagement: The effort and cognitive energy that students devote to mastering the educational objects.

Distributed Learning Environment: A learning environment in which participants are not co-located, but use computer-based technologies to access instruction and communicate with others.

Emotional Engagement: Students’ emotional responses (e.g. attitudes, relationships) to other people and content in the learning environment.

Flipped Classroom: An instructional approach where initial instruction in course curricula occurs prior to the face-to-face meeting and application activities occur in class so that the instructor is present to guide and provide feedback.

Hybrid Course: Another term for blended course—typically a course that replaces some F2F instructional time with computer-mediated activities.

Learning Analytics: The collection and analysis of data regarding learning performance and activity in order to understand the learning process and help individual students succeed.

Measuring Text Readability Using Reading Level

C

James C. Brewer

Texas Tech University, USA

INTRODUCTION

Reading Level is a calculation by formula which assigns a number to a text in order to represent the grade level at which a reader should be able to comprehend written English-language material. A variety of such formulas are in use, with the Flesch-Kincaid Grade Level as the best known and most widely used in the United States. The computation is supported by a variety of Web tools and by some of the most popular word processing tools. The formula is based on work done by Rudolf Franz Flesch (1911-1986) to develop the Flesch Reading Ease formula—as distinct from the Flesch-Kincaid Grade Level—which assigns a number between zero and one hundred twenty (120) to a text when expressing its reading difficulty. Zero means practically unreadable and numbers up to one hundred twenty (120) mean easier to read. (Theoretically, numbers less than zero are possible for extreme cases.) Examples are *Reader's Digest* at 65 and the *Harvard Law Review* in the low 30s. Note that for a journal, individual articles will be at different reading levels, and for this reason a journal will have a range or average value to describe its reading level. Following the work of Flesch, J. Peter Kincaid (1942-) used the Flesch Reading Ease formula as a basis for the computation today called the Flesch-Kincaid Grade Level. When comparing several different texts, the Flesch Reading Ease formula can be used as a measure of which of the texts is more difficult. The Flesch-Kincaid Grade Level allows a grade number to be assigned to reading material as suitable for that grade level.

Publishers of children's literature and school texts are often users of technologies to assign reading level to their published materials, but a much wider range of users can be found: producers of technical manuals which need to reach a range of educational backgrounds, those who create medical consent forms, and state and federal government agencies that produce documents covering insurance benefits or driver education manuals and tests, for example. Within the classroom or online education setting, reading level can also provide benefits to alert presenters and instructors about the complexity of the material that is introduced.

BACKGROUND

In mid-nineteenth century America schoolrooms were generally not divided into grade levels. Over time grade levels were added and methods were developed to measure the grade level of texts. As the need for graded material grew, there was an extensive push for more scientific methods to measure the grade level of specific texts used in the classroom. The result was the first readability formulas coming in to use in the 1920s. (Wolf, 2013) Much of the early work on the Flesch-Kincaid Grade Level formula was done by Rudolf Flesch in the 1940s (Flesch, 1979). Flesch had been conducting reading studies, observing readers and how they approach long words, and examining punctuation and sentence length. He was an active proponent of “plain English” and was known through many books, in particular *Why Johnny Can't Read: And What You Can Do About*

It (1955). He was a critic of the “look-say” method of teaching reading popular in the 1950s, and he advocated a method for teaching reading that became known as the “look and guess” method and started a revival of phonics which taught learners to sound out words using rules (Blumenfeld, 2015). The Flesch-Kincaid Readability Test and Reading Ease Test came about from the initial work of Rudolf Flesch and subsequent refinements by J. Peter Kincaid. These changes were added by Kincaid while performing work for the United States Navy. Noting that the Flesch-Kincaid grade level was developed for adults, J. Peter Kincaid pointed out:

Among other things we can reasonably measure: the number of commonly understood words, sentence complexity, the number of abstract ideas, and the use of personal pronouns. Beyond these factors, it takes the expertise of the writer and editor to judge organization of the text and whether or not the text conveys the proper information. (McClure, 1987)

In a 1987 interview J. Peter Kincaid stated:

I derived the formula [Kincaid Readability Formula] by testing a large sample of Navy technical personnel on their understanding of Navy technical passages. Next, I determined the personnel’s reading ability level with the Gates-MacGinitie Reading Test. I used a procedure devised for an Army study to calculate the actual equation. (McClure, 1987)

In the intervening decades after the original publication of the Flesch formula, many other formulas were published. It is the Flesch-Kincaid version which has remained the most popular formula over time.

The Flesch Reading Ease formula is given as

$$206.835 - 1.015 \left(\frac{\text{total words}}{\text{total sentences}} \right) - 84.6 \left(\frac{\text{total syllables}}{\text{total words}} \right)$$

(Flesch Reading Ease Readability Score, n.d.), which produces a number between 0 and 120. The higher the number, the greater ease in reading the text. The Flesch-Kincaid Grade Level is given as

$$0.39 \left(\frac{\text{total words}}{\text{total sentences}} \right) + 11.8 \left(\frac{\text{total syllables}}{\text{total words}} \right) - 15.59$$

(McClure, 1987), which then represents the grade level of the text (such as 6th grade level or 17th grade level, for example). Pennsylvania was the first state to require that auto insurance policies are written at the 9th grade level. (McDonnell, 2014)

A 1975 U.S. Navy report discusses in detail the sample size and the types of material which were presented for testing. The Grade Level formula was devised to assist the Navy Department in developing technical manuals so that the information is understandable to personnel who were being trained. The formula helped address the need to accommodate recruits over a wide range of reading skills. Goals included simplifying language through avoidance of synonyms, use of simpler words, and writing with a consistent sentence structure. (Kincaid, J.P., Fishburne, R.P., Rogers, R.L., and Chissom, B.S., 1975)

Nowadays, organizations that make use of Consent Forms (such as university research projects with test subjects) may find that the Institutional Review Board (IRB) will impose a Reading Level of 6th grade. This is often true for health organizations as well when asking patients to sign a consent form. The seemingly low Reading Level grade comes about in the following considerations. Participants called upon to sign a consent may be asked to do so in a short span of time, in an environment which is unfamiliar to them. By imposing a low reading level on the form, it is more likely that the language will be easier for the participant or patient to follow under a stressful condition and they will be much clearer about what is being asked of them. From the perspective of the author of a consent form, achieving the desired precision of language could prove difficult.

HOW TO USE THE FORMULA

Should writers check their own work for reading level? As the preceding discussion shows, the reading level numbers can help focus on problems with a text. The number alone may not have high significance by itself, but it does assume importance when the goals of the writer are to be considered. Who is the intended audience and what was the expected reading level? If these do not match up, it is a quick trigger to spend time editing.

How does the author determine the reading level of his work? Some word processing programs, such as Microsoft Word in its various releases, can be configured to provide the reading level of texts entered. Or texts can be cut and pasted into these programs from other sources and thus the reading level can be checked. Additionally, there are a number of free online websites which provide an online calculation of the reading level, generally by cutting and pasting text into a text window. A recent comparison of Microsoft Word and two online websites using the same texts showed reading level scores ranging over as much as one grade level or more. While this amount is not greatly significant, it does show that the computation of the score is implementation dependent. It would be wise to double-check any values used on multiple sources for the sake of consistency. Websites which accept PDF formats of a document will often show different Reading Level value scores of over a grade level when the PDF is converted to a Microsoft Word document and checked against those tools or websites which support other formats. This again is another indication that reading level checks available to authors are often implementation dependent.

In examining the Reading Level computation, it is noted that 'total syllables' is a component. Depending on how this term is computed, the resulting formula value as calculated may change. Electronic dictionaries used by word processing software or online services need to be up-to-date for a precise calculation. New terms, especially new scientific terms and foreign word borrow-

ings, pose particular concerns, since the rules of syllabification would be different. The actual mix of such terms becomes important if they are an overriding characteristic of the text.

There are several other observations from the formulas which should be noted as well. Both the Flesch Reading Ease and the Flesch-Kincaid Grade Level depend on total sentences and total words. This implies that the score may be more accurate when working with longer texts. Actual numbers on short sections of large texts will often fall within a grade level of each other as when compared to using the full text. Reading Level Grade should be viewed as a guideline rather than an exact indication on the scale of complexity in view of the variances described so far.

Both formulas also show that reading level can be improved (grade level reduced) by breaking longer sentences into shorter structures. To the extent that it is possible without loss of meaning, a more readable text will generally involve using shorter sentences. Consider, for example, the case of a translation from a foreign language: the translator should be aware that the original sentence length should not be preserved in most cases for an English-speaking audience, when content and not poetic elements are concerned. Consider, for example, the case of German scientific text which allows lengthy sentences of complex structure due primarily to the nature of German word construction and German grammar. Such structure should be reworked when the translated German content is presented to an English-speaking audience.

A writer can further determine which sections of his text are most in need of reworking by cutting and pasting selected sections into a word processing program that does the reading level checks. In this way, it is easier to isolate specifically where to make the changes leading towards simplification.

In summary, users of the computations should pay close attention to the following:

- Applying the formulas to longer texts will be more accurate. For example, on a short consent form, one long or complex sen-

tence alone will cause the reading level value to be high, compared to when that longer sentence is broken into shorter sentences.

- Sentence length plays an important role in the calculation. When considering a verbal presentation to an audience, not only is the overall complexity of the text reduced, but listeners will be given a better chance to follow the discussion that they are hearing for the first time.
- Note that neither the Flesch Reading Ease Formula nor the Flesch-Kincaid Grade Level takes into consideration the overall editorial objective of conveying ideas clearly and without undue complexity. These are issues which should be addressed by editors prior to making a determination about reading level of a text using the computations. The formulas should be applied on documents and writings after the editing phase has taken place and clarity of the overall presentation has been worked out.

Users of the formulas should understand that Reading Level calculations need to be evaluated in terms of intrinsic factors of the text which is being analyzed. Technical documents in medicine or chemistry may borrow from Latin and Greek roots and produce a type of English resulting from the construction of neologisms that is not easily measured with evaluative tools. Such situations would suggest that Flesch-Kincaid formulas will not apply well, since these do not take into account the significance of these terms from other sources.

Many writers who have learned a foreign language know that there are often terms which are not easily translatable into English. The converse is also true: many English words do not have direct equivalents in other languages, a fact which poses unique problems to readers from specific cultures. Writers will of course have no idea of the native languages of their potential readers and what pitfalls to avoid in their word choices. This issue looms larger when the context is sci-

entific papers, which are the principal means by which new findings are communicated to broad audiences. Writers of scientific papers can often have limited training in composition beyond their secondary education. Since English is most often the primary discourse for science, speakers whose native language is not English will be writing in a language choice which can pose significant obstacles. While spelling, punctuation and grammar will be corrected by automated tools and careful editors, the conceptual design of the article may reflect the non-English word choices and syntax of the writer's native skills. Scientific integrity does not always correlate with the ability to write simply. Writing is a skill that must be acquired through instruction and practice.

Manual computation of the formulas is ill-advised, especially for longer texts, since this involves counting syllables, words and sentences. A wide range of tools are available online, many of which are freely available (Readability Formulas, n.d.). Free tools cover a range of different formulas and scores, such as the Gunning fog index, the SMOG Index, the Coleman-Liau Index, Automated Readability Index and Linsear Write Formula. Recall that Rudolf Flesch mentions in the 1950s alone two dozen competing formulas existed for the purpose of computing reading level, each with their own specific approaches but offering similar information. A brief digest of these formulas is given in Table 1. Table of Common Reading Level Tools, which follows below.

Many users of the Flesch-Kincaid Grade Level or Flesch Reading Ease Formula will want to rely on Microsoft Word for these computations, which can be configured as part of the word count computations that are available in the tool. Microsoft Word could be used for text created within the tool itself or for texts cut and pasted in the tool. Conversions exist so that Microsoft Word can import PDF files. Details to enable this computation should be determined from the Help file for Microsoft Word, since specific settings may change depending on the software release.

Table 1. Table of common reading level tools

Tool or Formula	Description
Flesch Reading Ease formula	A number from 0 to 120 to evaluate the relative ease of reading a given text. Can be used to compare texts and determine which are more easily read. Lower numbers reflect greater reading difficulty, and higher numbers reflect greater reading ease.
Flesch-Kincaid Grade Level	A decimal number that translates roughly as the grade school, high school or college level grade of text readability.
Gunning fog index	Developed by Robert Gunning to measure number of school years needed to read a given text.
SMOG grade	SMOG stands for the “Simple Measure of Gobbledygook” and attempts to measure the number of years of education needed to understand a text. It was widely adapted in health care.
Coleman-Liau Index	The index is another alternative to the Flesch-Kincaid Grade Level and assigns a grade level number relating to the United States usage of grade levels. The index is intended to be one that can be applied manually from a text.
Automated Readability Index	The index is an alternative to the Flesch-Kincaid Grade Level Formula, and is used for English language materials. The index attempts to supply a grade level number relating to the United States usage of grade levels. This index makes use of characters per word instead of syllables in the word.
Linsear Write calculation	The Linsear Write calculation was developed by the United States Air Force for determining the readability of technical manuals. It relies on manual calculation and takes note of words that have three or more syllables.

Reading Level is an active area of research, particularly in professional areas such as medicine which need to bridge the gap between research findings and helping the public to understand these results. (Neuhoff, 2016) Moreover, writers can benefit from the number of well-crafted websites which provide reading level tools to measure the complexity and accessibility of their writing, whether fiction or non-fiction. (Readability Score, n.d.) Researchers are addressing issues such as achieving useful, readable publications and working with readership. Surprisingly, lower reading level can correlate positively with commercial popularity of publications.

CHALLENGES ON THE INTERNET

English has become the de facto standard on the Internet. This fact alone simply informs us that many users who are not native English speakers are reading from and producing Web information. Depending on the countries of origin of the readers and writers, access to resources for reading and writing in English can vary greatly. Even where resources for language learning and language reference are available on the Internet,

questions about bandwidth, firewalls and paywalls, and device capabilities start to play a role. Online tools are now available to check the reading level of a website. (Checking the Reading Level of Your Website, n.d.)

Reading Grade Level formulas are generally not discussed outside the English-language context. Several considerations can help to explain this phenomenon.

- The English language has among the highest word counts of all languages. Depending on estimates used and the types of words included, totals run from several hundred thousand ordinary words to over one million for complete dictionaries with foreign borrowings and all scientific terms and chemical names. (Global Language Monitor, 2014)
- English grows rapidly over time due the force of the language as the principal language of science with the resulting inclusion of new terminologies to accommodate the advancement of sciences. According to a recent estimate, a new word comes into the English language every 98 minutes. (Global Language Monitor, 2014)

- English is widely taught to students of all levels of income, background and ethnic origins, due in part to the United States educational policies of inclusion, perhaps among the widest number of groups, cultures and backgrounds.

Thus, English presents special concerns in its ability to allow widely different kinds of texts with a proliferation of related words offering fine shadings of meaning. The fact English is a growing language that borrows freely from all areas of the world makes it challenging to define proficiency. In order to successfully reach a diverse audience, measures such as Reading Grade Level computation can help to a greater degree by bringing standards to the evaluation of texts for use in a range of educational purposes. Many other language groups have relatively restrictive boards or organizations which monitor new material coming into the language and reject newly constructed foreign terminologies in favor of native word formations or native word roots.

CONSIDERATIONS FOR NON-NATIVE ENGLISH USERS

Today the abundance of translation tools (browsers and applications) reduces the need for the reader to rely on English solely and may in fact over time weaken English language skills due to lack of practice. When it comes time to write in English, the non-native writer would be facing a steeper climb as the result of nonuse of his language skills. In effect translation tools reduce the importance of mastering English unless the user needs to write in English. This scenario further supports the idea of English as a base global language, regardless of the reader's native tongue, since he can easily get to an equivalent in his mother tongue from English, whatever the native language is. The translation tools further the idea that English can retain its prominence in terms of language representation over the long range, carrying the

idea into further generations of Web users. It may also be of significance that in U.S. higher education foreign language study has declined through the weakening of language requirements and the decline in faculty positions. The implication here is that those writing in English-speaking countries become less aware to the complexities in writing for a foreign language audience.

A faculty member could check planned readings from the Web before these become assignments. Rather than omitting specific readings, more preparation could be given to students in the class when reading level scores show very high values for texts that will be assigned reading. It is easy to select sections from a text and examine reading level by cutting and pasting sections into a tool which does the Flesch-Kincaid calculation. While native speakers of English may not experience difficulty with many texts--even when the reading levels are high--many classrooms today have a mix of students from a variety of ethnic backgrounds and reading abilities. Preparing focus questions for review that single out the difficult sections of the reading can prove valuable in bringing student understanding forward.

When faculty members are developing an article or a presentation, working with the Flesch-Kincaid calculation could prove beneficial. A verbal presentation will benefit from a lower reading level value, even when publication is intended. When listeners are seated for a presentation, they can be greatly helped if the material has been screened for unnecessary complexity. But it should never be assumed that Flesch-Kincaid will detect all problem areas. Areas that can be focused on when delivering a written talk verbally include the following: long sentences, complex sentences, and word length. It is important to stress that oversimplification in this area is not intended, but it is a way of calling attention to areas which can create challenges for listeners. Naturally, careful inflection of words, insertion of pauses in materials presented, and slowing down during difficult passages can be especially beneficial and more productive than rewriting.

Due to the need to have published conference proceedings, presentations are frequently given as material read before an audience. The speaker's familiarity with the content may further result in obscuring the content since the challenges of a first listen will be lost to the speaker. Awareness of these issues is the best insulation to preventing them from happening.

A number of other methods can be used in conjunction with Flesch-Kincaid to assist with producing documents that are to be read before a group. Many researchers have showed that when writers make use of multiple senses (e.g. hearing, sight) during writing, the result can be significant. It is therefore reasonable to bring sound into editing a text. A number of editing tools will read back in spoken form text that is being written. This allows the writer to bring in his sense of hearing along with the writing skill in a way that can produce a more acceptable result. When writing, using a voice recorder can help in a number of ways by taking advantage of playback. Spoken material will allow additional skills to come into use, and the writer will be able to both hear and record his intentions. A number of tools exist to take the recorded voice file and convert to text in a highly accurate manner. Or the writer can use one of the computer tools that directly convert spoken material into computer text. Another method that is of great value is to be able to listen to existing text from a computer file spoken by a variety of voices, male and female and with various voice styles or accents.

FUTURE RESEARCH DIRECTIONS

The topic of reading level continues to reemerge in very active discussion among educators due to a variety of issues. Generations of teachers with distinct differences in how reading should be presented have come and gone. New forms of media have come about from the growth in technologies. The entire public is called upon to view more information, often in electronic format, with

little guidance on how to evaluate what is being read. Questions about literacy come to forefront as standardized tests show areas of deficiency even though methods abound to address such concerns. As schools change their structures and reinvent themselves, where do the traditional skills that had emphasis in the past now fit in a new place?

Current research in reading now includes bringing in new technologies such as fMRI, which can identify the areas of the brain that are involved in specific activities relating to reading. In fact, it is possible to make use of fMRI in many cases to pinpoint those students who are currently experiencing or will encounter reading difficulties. (Dehaene, 2009) As a greater understanding of the biological aspects of reading is gained, it will be possible to redesign reading programs to address specific brain functions and more precisely measure results.

CONCLUSION

Reading Level is an important tool for publishers for a variety of audiences, from students learning new material to those who are studying training manuals to become proficient in a new skill. The Flesch-Kincaid Grade Level can be helpful to authors in creating their texts by providing an objective measure of the complexity of the material. The resulting computation can indicate to the author if the material is suitably targeted for the intended audience. When Internet publication is planned, this will also help with reaching non-English audiences who may experience difficulty with more complex texts as determined by the Grade Level computation. Faculty members can also make use of the Flesch-Kincaid Grade Level as a measure of complexity when making reading assignments. In the case where the material is especially difficult, the techniques described here can point to the need for further follow-up classroom discussion or giving additional information prior to reading assignment to alert students to the more challenging material. (Readability Score, n.d.)

KEY TERMS AND DEFINITIONS

Automated Readability Index: The index is an alternative to the Flesch-Kincaid Grade Level Formula, and is used for English language materials. The index attempts to supply a grade level number relating to the United States usage of grade levels. This index makes use of characters per word instead of syllables in the word.

Coleman-Liau Index: The index is another alternative to the Flesch-Kincaid Grade Level and assigns a grade level number relating to the United

States usage of grade levels. The index is intended to be one that can be applied mechanically from text. It relies on the average number of letters per 100 words and the average number of sentences per 100 words.

Flesch Reading Ease Formula: The Reading Ease Formula was developed by Rudolf Flesch to provide a number between zero and 120 to represent the difficulty of a text. Theoretically, there is no lower bound to the number assigned. Lower numbers represent greater difficulty and higher numbers represent greater ease of readability. For example, *Reader's Digest* is around 65 and the *Harvard Law Review* is around 30.

Flesch Kincaid Grade Level Formula: The Flesch-Kincaid Grade Level Formula was originally developed by Rudolf Flesch and further revised by J. Peter Kincaid while working on evaluating the reading level of technical manuals for the United States Navy.

Gunning Fog Index: Robert Gunning developed the Gunning fog index in the 1950s to measure the number of years of school that would be required to read a given text. For example, a fog index value of 17 would require a college graduate.

Linsear Write Calculation: The Linsear Write calculation was developed by the United States Air Force for determining the readability of their technical manuals. It relies on manual calculation and note of words that have three or more syllables.

SMOG Grade: SMOG stands for the “Simple Measure of Gobbledygook” and attempts to measure the number of years of education needed to understand a text. It was widely adapted in health care.

Multimodal Literacy

Maryann Tatum Tobin

University of Miami, USA

INTRODUCTION

Reading in today's technology-rich world has become an increasingly complex maze of symbols, systems, and patterns. Current research in the field of literacy proposes an updated, more robust definition of reading that extends beyond traditional printed text to include reading-to-learn as a multimodal activity incorporating emerging technologies into daily literacy instruction. Heath & Street (2008) define multimodal literacy as the ability to navigate the "combined representations of written, oral, visual, and gestural systems of communication." However, the implication on educators is such that additional modifications to pedagogy must take into account the ever-changing nature of media. Generational terms such as *digital natives* (those born after the year 1980s) (Prensky, 2006) and *millennials* (those reaching young adulthood sometime around the year 2000) hardly encapsulate the huge difference between growing up with an offline home/micro-computer in your home to the vast array of knowledge available by spending your childhood with a smart phone in your hand. Digital natives process information in a vastly different way than previous generations, however, "native-ness" with technology and the ability to use it to learn in efficient ways are not always synonymous. Facility with social media and multitasking does not equal deep understanding or a natural instinct on how to program or create media for and about learning. Curriculum and schooling has begun to change to accommodate this world of hypertext, distance, and simulated learning, but many scholars find that change has not come fast enough to keep up with the pace required by the exponential growth of technology. For example, in the field of literacy

education and the teaching of reading, the effects of technology on the classroom environment, and most-specifically how the truncated and fast-paced world of online, shallow reading has affected the reading and learning stamina of children saturated in media (Carr, 2010). These critical factors are what will dictate the knowledge capacities and learning modalities of today's children and future generations.

BACKGROUND

Since the latter part of the 20th century, the traditional notion of literacy has been redefined. Just as the invention of the printing press moved society into the typographic culture, now we are in what Provenzo (1986) termed the "post-typographic culture," where the definition of a literate person now includes affinity with the computer, media, and visual literacies. In the post-typographic world, microcomputers revolutionized commerce and news media, but education is still late to the game. There are pockets of classroom use, but by comparison to how, for example, marketing, was transformed by social media and online metrics, education has largely seen isolated use of technology. However, within the last decade, tablet and portable device-driven learning has begun to see a more comprehensive change, and print books are taking a "back seat" to multimedia in the school life of students. Print-based texts contain elements of written language, images, and design elements such as typography and graphic design, but media-rich texts involve moving images, sound effects, and increasingly robust digitally-rendered elements that must be "read" by students (Sarafini, 2014).

DOI: 10.4018/978-1-5225-2255-3.ch130

Many students are immersed in media-centered environments that are different from classrooms of the past. This new technology comes with several acquired understandings for young readers, as they must learn to maneuver their way through both print text and a series of icons, images, and symbols. Literacy instruction, therefore, the “becoming literate” has moved from an ability to navigate and decode a printed text for the purposes of gaining new knowledge to the ability to access, manipulate, and apply information from a variety of print and non-print courses (Gee, 2007). These new literacies require a pedagogical revolution that incorporates processing a variety of modalities simultaneously in the classroom. Engagement with robust new literacies helps prepare students to not just be receptacles of information, but to think critically, observe and evaluate like scientists and historians (Abilock, 2001). To foster inquiry and project-based learning, schools are developing links between content area teachers and the central texts (both print and digital) through *disciplinary literacy*, that is the confluence of content knowledge, personal experiences, and the ability to read, write, listen and speak academically (Wineburg & Resiman, 2015).

Engaging students in open-ended, authentic, problem-based tasks using technology has become the key to this kind of transformative learning (Wiggins & McTighe, 1998). Technology has been, for many disciplinary literacy scholars, a blessing in that a myriad of open access resources are now available to learners. However, this blessing has also created a curse. Most of the text available online are less dense and more truncated than ever before. Imagine the difference of reading the New York Times cover to cover versus getting the news in pop-up updates from your CNN app. The fast-paced world of online reading is the demand of the day. Although we may long for the times when deep reading was valued, the machine of automation has driven society forward and the field of literacy education is no different. To paraphrase Marshall McLuhan, we cannot drive the information super-highway by looking in the

rear-view mirror (1964). However, literacy educators today fight a constant battle to combat the foundational pangs of “shallow-reading,” including poor reading stamina, shorter attention spans, and the inability of students to show motivation to read anything that appears time consuming or lacking in value (Carr, 2010).

Digital Natives?

In the literature, *digital natives* and *millennials* are often used interchangeably, although there has been some considerable debate about whether or not the distinction still holds relevance. Both terms have come to refer to the same social group: those born after 1980 that have become working adults around the turn of the 21st century. The modern educational system is currently populated by both *digital natives* and *digital immigrants* (those who have learned to use the technology as adults). In fact, many of today’s teachers are also by definition *digital natives*, although many argue that the level of native-ness varies greatly between those born in the 1980s and those born today. Having a computer with dial-up Internet in your home as a child is quite different than having a smart phone in your hand at all times. Classroom teachers must navigate the distance between their own technological knowledge and skill and the technological fluency of their students, and that savvy with technology has been pared down to a fundamental difference between how digital natives and digital immigrants think.

McLuhan commented that “we shape our tools and thereafter, our tools shape us” and part of that shaping includes reshaping how students acquire, retain, and exchange information. Take communication, for instance. To a digital immigrant, long-distance telephone communication was something that was once expensive and limited, almost a novelty used only by those who could afford it. Letter writing and post-cards were the medium of choice when communicating with those distant cousins. But, to a digital native, real-time connections across the world via text messaging

services and apps are commonplace and in many cases, free. In fact, in an effort to abbreviate communication even more so, truncated texts, slang, and emoticons provide for casual multimodal connection so that natives can efficiently and thriftily communicate information in fewer characters or exclusively through images.

Digital natives act as both content consumers and content creators. Termed “Dot Nets” by Pew’s Research Center because of their facility with navigating the complex geography of the Internet, millennials are comfortable using a diverse range of media to

multitask, and they “demand interactivity as they construct knowledge” (Bauerlein, 2009, pg. 73). This issue of multitasking, though, has mixed challenges for literacy educators. During homework, for example, students often deal with multiple inputs from friends, family, and school all simultaneously. This presents a few important issues for educators (and parents) to consider:

- Mental downtime from media to encourage the development of other parts of the brain.
- Sleep disruption due to too much digital stimulation.
- Other distractions produced by digital devices (such as driving distractions).
- Addiction behaviors towards digital devices (Steyer, 2012).

Splitting focus is nearly impossible, even for the mature brain. Humans are unable to effectively process two streams of informational stimuli at once, and while hypertext has been credited with increasing informational access, reading motivation, fast problem-solving and data-juggling, it is often also related to limited attention span, skimming, cognitive overload, and diminished long-term memory (Steyer, 2012). Much of homework multitasking involves double screens and browsers open to television and video services, like Hulu and Netflix, and the market certainly has not missed this opportunity. In fact, in 2014, Nielsen’s rating service began measure YouTube view and found

that it reaches more 18-35 year olds than any cable network (YouTube Statistics, 2016).

This culture shift has called for many technology activists, like Marc Prensky and Jonathan Fanton, to declare that perhaps the richest learning environment we could offer young people is no longer the traditional classroom. *Flipped learning* allows for students to take advantage the web’s wealth of content independently and then come to the classroom for teacher-facilitated cooperative inquiry. Fine for the student who reads well and learns well independently, but quite a challenge for the fifth grader who still struggles with basic literacy skills like decoding and phonics. Naysayers of flipped learning model critique the reliance on low-income students’ home access to efficient connectivity, those who have to share limited computer time with family, or those students who simply do not have the time and focus to watch a direct instruction lesson online. However, the flipped model does show benefits in extending teacher time during the day and allowing for more time for students, especially those with exceptionalities, to have more one-on-one time with the teacher (Weisen, 2014).

A challenge of such increased screen time is that screen intelligence doesn’t always transfer to print experiences (Bauerlein, 2009). While the Internet’s saturation of videos and music does train the brain to be adept at processing multiple stimuli simultaneously, what it does not promote is understanding for deep meaning. Media-savvy minds are open and flexible to what grabs their attention, but the “digital mind” turns away from the one-dimensional printed text. In fact, many of the new standards for college and career readiness purported by educational systems urge the use of technology to “master the kinds of higher-order thinking and decision-making skills employers seek today” (Federation of American Scientists, 2006).

So how do we reconcile the fact that today’s college graduates have spent less than 5,000 hours of their lives reading and over 20,000 hours on the computer, watching TV and playing video

games (Prensky, 2011)? Are we simply leveling up to meet the promise of the new world, just as 15th-century civilians did with the arrival of Gutenberg's printing press, or are we fulfilling a Kubrick-like philosophy of succumbing to the individuality-numbing of artificial intelligence (Carr, 2011)? Fatalists would believe the latter. But, educators, who have been confronted since the dawn of modern schooling with the "latest and greatest" new fads have learned to adapt instruction to meet the ever-changing needs of young minds. As an example, Gee (2007) presents several principles of learning in his study of the self-directed learning that takes place as students engage in playing video games, including critical learning, the use of semiotics, the development of a metalanguage for and about learning, and the understanding that text is an "embodied experience." As learners negotiate multimodal texts, initial, mostly verbal understandings, give way to larger, cross-modal understanding that involve the "reading" of images, sounds, renderings, actions, and consequences.

In the case of reading, which is the first window onto the world presented to any young mind, preliminary exposure to texts in the modern toddler is often digital in nature (mom's iPhone or dad's e-reader). But it is still exposure to print nevertheless. In fact, the draw of technology is often a gateway to new and deeper exposure to text (Tobin, 2012). Reading teachers and educators who tackle reading in the content areas have come to adopt a new and deeper paradigm for creating literate learners.

Multimodal Literacy Learning

The term "literacy" and the meanings to which it refers have changed in recent years. People who could not read and write printed letters were often considered to be illiterate, as early definitions of literacy encompassed decoding, mastering the alphabetic principle, effectively communicating with texts, learning grammar and sentence structure, comprehension, and becoming an expressive,

persuasive, or informational writer (Moje, 2003). However, the advent of technology in schools extended the notion of literacy to "the practice of navigating many different symbol systems and discourse communities to make meaning from and with written text" (Moje & Sutherland, 2003, p. 152). People who can only read and write alphabetic letters are viewed as lacking the appropriate literacy skills vital to the digital age, which is characterized by images, sound, videos, and other texts on various screens. Thus, the term *multimodal literacy* has emerged, representing the combined representations of written, oral, visual, and gestural systems of communication provided by technology or other media (Heath & Street, 2008; Kress, 2000).

The main difference between reading in a print-only world and reading online is that text in a world of hypermedia is rife with choices. The market is such that we are inundated with images and distractors that encourage us to click away from what we are reading or doing online. The pitfalls are many, not the least of which is to develop in young readers the core competencies of research: targeted reading, making informed judgements, and culling information from a variety of sources, which is termed *informational literacy* (Gilster, P., 2000). Digital immigrants, therefore, were taught to read in a print world but have learned to adapt their reading focus and stamina to the online world. This dichotomy is illustrated by Knobel and Lankshear (2007) who developed a two-threaded definition of "little 'l' literacy and big 'L' literacy." Little 'l' literacy is the traditional, print-based, foundational view of literacy: the actual processes of reading and writing. In contrast, Big 'L' literacies are connected to the patterns and discourse that integrate ways of communicating through gestures, actions, spoken and written words, images, and sounds. This kaleidoscope of literacies is still conceptualized in relations to text, but now *text* is defined as any instance of communication using any semiotic resource (Kress, 2003). Research has found that the inclusion of new technologies, even with

early readers, provides for new resources for both students and teachers, and the potentialities to increase the development of little 'l' literacy skills.

(Leu, Kinzer, Coiro, & Cammack, 2004; Lankshear & Knobel, 2006; Ranker, 2008). One of the fastest growing big 'L' literacy is *media literacy*, which is defined in relation to a person's attitude toward, evaluation of, and experience in reading texts and designing hypertexts made possible by technology (Hobbs, 2007). A key tenet of multimodal literacy learning is that digital natives draw from a prolonged access to social networks and informational materials, computer editing programs, and constantly changing communication technologies. So, being literate in today's media-rich world includes recognizing and negotiating the social positionings inherent in the exchange of both prolonged and immediate interactions with a variety of multimodal texts (Alvermann & Hagood, 2000).

Shallow Reading

While the average child today may spend exponentially more time in front of a screen than their predecessors, their facility with technology is often limited to "surface technologies" like texting and social media. This parallels what Nicholas Carr calls "shallow reading" – where skimming and scanning are valued and contemplation and reflection are lost (Carr, 2010). What we need is a way to bring deeper and more meaningful interactions with technology into the classroom so that students are exposed to more complex digital tools like HTML codes, programming, and spreadsheets, and we need to train educators to bring deeper intellectual discussions to social media platforms for student consumption, so that the surface technology becomes an outlet for rich discussion.

Careers in the sciences, particularly medicine, still rely heavily on linear thinking and development, as opposed to the creativity and entrepreneurial thinking that may await a career at Google. So there is still a need to focus on little 'l' literacy

learning methods to some extent in classrooms, otherwise reading stamina and focus is lost in the fragmented world of online reading (Carr, 2010). The world cannot be "de-technologized," so educators must learn to teach linear processes in a non-linear world.

FUTURE RESEARCH DIRECTIONS

In order to train literacy educators to be successful in preparing young minds for whatever demands are placed on them regardless of career path, a healthy balance of collaborative learning and "do-it-on-your-own" learning must be presented. We must be prepared to plan literacy across language, modes, media, ideologies, and cultures (Hull & Nelson, 2009). Old paradigms have been hard to change, but most school systems have accepted the call to implement best practices for 21st century learning, including shifting the instructional focus from the teacher to the student (Tapscott, 2009).

Broadcast Learning vs. Interactive Learning

This is the main shift in education that needs extensive continual study, especially given the high-stakes testing mentalities that the latest research is working hard to combat. The focus on learning needs to not be about what students know when they graduate but on their capacity for lifelong learning and their metacognitive awareness of how they learn and collaborate best. When presented, for example, with a multimodal literacy lesson, which modalities do they prefer to use and which modalities help them learn more efficiently. Each modality comes with its own semiotic metalanguage for and about the activity. In other words, each learning tool comes with its own set of rules for interactions. If a reader finds that listening to music helps them focus, then the teacher needs to encourage that. If stopping for questions or supplementing a text with video improves comprehension, then the

teacher needs to incorporate than into his/her lesson planning. This is the malleable nature of a truly multimodal classroom. Broadcast learning, which is very teacher-centered with a “sage on stage” is passé. Interactive learning should rule the day. Classrooms should be learner-centered, collaborative, and based in inquiry and discovery (Tapscott, 2009).

Micro-Level Literacy

With all the focus on multimodal literacy and its affect on changing the way we view reading and thinking as a society, we must not lose sight of the foundational, little ‘I’ literacy practices that promote linear learning. Micro-level literacy promote basic skills that transition across subject areas and are transferable resources available to students throughout their academic lives (Ivanic, 2010). Previous micro-literacy studies focused on transferring skills in the narrow framework of class-to-class – in other words, making sure that what is learned in a reading class is able to be used independently to understand a text in history or science classes. Teaching students to scale their micro-level skills to the macro-level in the digital world provides a framework for refining communication and inquiry within the global community (Brown & Slagter van Tryon, 2010). Understanding the micro aspects of something instantaneous like a tweet and how it can impact networking on a macro-level is a key 21st century literacy skill that needs further study in the context of the digital world.

The Global Marketplace

This is an unparalleled time in literacy education, where new technologies have provided opportunities to create educational paradigms that cross cultural and linguistic boundaries (Zapata & Roach, 2011). The ideology of multimodality is one that promotes social semiotics and transcends the boundaries placed on us by global borders. We must study how to best prepare young consumers

of knowledge to be aware of the hypermobility that being literate provides and the positions of success granted to those who attain literacy. We must also study the effects of those who are not advantaged in greater detail, as the digital divide can continue to stratify those without access on broader, more global levels.

CONCLUSION

We read everyday. We read text, facial expressions, actions, signs, patterns, and symbols. Most of what we do as literate members of society is automatic, as we have reached a level of fluency, learning to read with print and adapting to the digital world. For digital immigrants, while seemingly disadvantaged by the digital native-ness of the young, the benefit of learning in a micro-literacy world and adapting to a macro-literacy world must not be diminished. It is this facility that allows for the true understanding of how to develop curriculum for a multimodal world. Through multimodal literacy, teachers and students, collaboratively, can explore the changing nature of reading using different semiotic resources across a variety of modes. Adapting instruction and schooling to this new reality will develop more robust learners prepared for the challenges of the rest of this century and beyond.

KEY TERMS AND DEFINITIONS

Big “L” Literacy: Literacy connected to the patterns and discourse that integrate ways of communicating through gestures, actions, spoken and written words, images, and sounds (Knobel & Lankshear, 2007).

Digital Immigrants: An individual born before the widespread growth of digital technologies.

Digital Natives: Being “born digital,” “native speakers” of the digital language of computers, videos, video games, social media and other sites on the internet (Prensky, 2001).

Disciplinary Literacy: The confluence of content knowledge, personal experiences, and the ability to read, write, listen and speak academically (Wineburg & Resiman, 2015).

Flipped Learning: An educational model in which content is delivered to the student independently through videos and web content, followed by classroom times for teacher-facilitated cooperative inquiry.

Hypertext: Text displayed on a computer or other digital devices that has embedded hyperlinks,

images, or media that can be accessed to enhance the primary text.

Informational Literacy: The ability to access and cull information from a variety of print and non-print sources.

Little “l” Literacy: The traditional, print-based, foundational view of literacy: the actual processes of reading and writing (Knobel & Lankshear, 2007).

Media Literacy: The experience of reading texts and designing hypertexts made possible by technology (Hobbs, 2007).

Millenials: A demographic cohort representing anyone born between 1980-2000.

Multimodal Literacy: The design of discourse (for example, language, gesture, images) co-deployed across various modalities (for example, visual, aural, somatic) as well as their interaction and integration in constructing a coherent text.

Shallow Reading: The practice of reading quickly, in truncated forms (e.g. texts, images, memes), without critical analysis.

Text: Any instance of communication using any semiotic resource (Kress, 2003).

An Open Learning Format for Lifelong Learners' Empowerment

C

Sabrina Leone

Università Politecnica delle Marche, Italy

INTRODUCTION

Open learning and lifelong learning (LLL) are not new concepts in research literature (Brügelmann, 1975; Coffey, 1988; Kent, 1987). Anyhow, the current fervid debate is on the need for disruptive education at the light of the fundamental technological and societal changes that have occurred in recent decades (Stevens & Kirst, 2015). The whole life course is being reworked. Open, lifelong and ubiquitous learning, cloud computing and smart city frameworks are the pillars of the change that is replacing the traditional education and work models and transforming the way crowds of people learn, communicate, collaborate, teamwork, produce value and growth for the entities of which they are part (Leone & Biancofiore, 2015).

Education systems are urged to meet the growing demand for personalised learning paths, and individuals are driven to acquire awareness, tools and competences towards personal learning goals.

In particular, emerging practices with social semantic computing technologies and research findings signal the need for more personal, social and participatory approaches that foster learners in co-producing learning resources, rather in managing the learning process as a whole, and in pursuing personal life goals and needs. Indeed, learning occurs increasingly for the most part outside the traditional formal situations, especially for adult lifelong learners (European Commission/EACEA/ Eurydice, 2015).

In this regard, over the last years highlighting on the shift from formal to informal eLearning through knowledge management and sharing has been placed. Growing attention has been paid to

Personal Learning Environments (PLEs) as an effective framework for lifelong learners, and to the need of integration of formal and informal learning. Formal teaching spaces are defined within Learning Management Systems (LMSs). Spaces agreed in informal learning communities, instead, are to be used by social software. They are aimed to build networks of virtual identities and to define PLEs of dynamic contents, based on continuous accesses, validations, dialogic exchanges. ELearning 2.0 has mediated the shift from formal to informal eLearning, from LMSs, which are organisation-centred spaces that overlook individual differences and potential, to PLEs as emerging learner-centred spaces.

A wider and wider range of open source and free learning applications on the web are offering lifelong learners powerful tools to construct and characterise their own PLEs.

Technologically speaking, this change of perspective manifests in a learning web where information, activities and relations are distributed across sites and web-based learning applications, of which social networks have become a key factor. Consequently, knowledge management becomes an issue, and personalisation requires the support of adaptive mechanisms and of semantics applied to social components.

This work presents the updated version of *SSW4LL* (*Social Semantic Web for Lifelong Learners*), an adaptive, modular, flexible and integrated learning format which has been devised to support the characterisation of adult lifelong learners' PLEs by implicit and explicit tools of personalisation, in a learner-centred framework (Leone, 2013; 2014; 2015). The *SSW4LL* system,

the technological architecture, is presented as a whole made up of components of formal and informal learning environments: Moodle 2.9 integrated with an adaptive mechanism (conditional activities) and some tools of Social Semantic Web (Semantic MediaWiki 2.3, Diigo and Google+), respectively. The *SSW4LL* format was successfully validated during the course *SSW4LL 2011*.

BACKGROUND: PERSONALISATION IN A LIFELONG LEARNING VISION

Over time a great amount of theories and definitions of personalisation of learning have been produced. The expressions *personalised learning*, *personalising learning*, *individualised learning* have been coined to characterise and support with different emphasis the basic common view that each learner should be able to choose a tailored learning path, in order to meet personal needs, interests and abilities (Bentley & Miller, 2004); to promote both independence and dependability (Downes, 2007); to enhance social skills and sense of responsibility toward others (Pankhurst, 1922; Keller, 1968); to improve creative, intellectual, social and moral growth and develop personality fully (OECD, 2006; Rogers, 1983).

As the activator of economical, cultural and social growth of the knowledge society, the individual should be seen as an active, responsible and self-motivated learner, a co-author of the script that determines how education is delivered (Knowles, 1970; Leadbeater, 2004), often with extensive use of technology in the process; briefly, a lifelong learner (Leone, 2010; Martinez-Pons, 2002; Zimmerman, 2002).

The emphasis in relation to personalising education is that learning is inclusive, lifelong and therefore reaching beyond the traditional confines of schools (OECD, 2006).

Personalisation is thus a strategy aimed at designing, implementing and supporting learner-centred institutional practices (Maharey, 2007), and at drawing on wider resources for learning

beyond formal education, by creating new flexibilities to meet new demands (Bentley, 2005).

In this regard, Leadbeater's model of surface and deep personalisation (Leadbeater, 2004), where the student steadily progresses from consumer to producer behaviour, calls attention to a great deal of crossover with PLEs.

Since its appearance, the concept of PLE has posed numerous educational theories and implications (Chatti et al., 2010; Downes, 2010; Leo, Manganello & Chen, 2010; Motschnig-Pitrik & Mallich, 2004; Pettenati, 2010; Wild, Mödritscher & Sigurdarson, 2008). In this research, a PLE is a concept rather than specific software, a group of techniques and a variety of tools to gather information, explore and develop relationships between pieces of information (Leone & Guazzaroni, 2010). A PLE helps to view the subject as a landscape as well as individual pieces of information; to create a personal repository of materials and relationships clustered around a unifying topic or concept; to document, reflect, communicate, collaborate. Information and knowledge reside in digital and non-digital sources. A PLE, at the same time, develops and is fed by autonomy, pragmatics, relevance, building on prior knowledge, goal-directed approach (Leone, 2009).

Certainly, the concept of PLE has challenged the existing education systems and institutions, since new forms of learning are based on trying things and action, rather than on more abstract knowledge. Thus the dichotomy LMS vs PLE has been transformed into models of integration (Giovannella, 2008; Leo Manganello & Chen, 2010) of formal and informal learning.

Anyhow, in relation to personalisation of learning, LMSs, the formal component of the integrated learning environment, are weak (Graf, 2007), and the management of an effective PLE requires information overload and diversity, distribution, trustworthiness and evaluation of the collection of learning resources to be tackled as critical elements.

To this end, adaptive mechanisms and Social Semantic Web can offer suitable tools of

respectively implicit and explicit personalisation (Braynov, 2004) of learning. Implicit learner's profiling is automatically carried out by the LMS through an adaptive plug-in by tracking and monitoring user's behaviour in order to identify learning patterns. Explicit profiling, instead, involves the learner's active participation by Social Semantic Web tools, thereby allowing the user to express directly needs and modalities and thus to control and share his/her learning path.

Many pedagogical and psychological theories sustain that learners have diverse learning modes (Felder & Silverman, 1988; Gardner, 1983; Kolb, 1984) and that students showing a strong preference for a specific learning style could have difficulties if the teacher's approach is dissonant (Felder & Soloman, 1997). On this basis, the evaluation of the several models for the detection of learners' learning styles and of adaptive educational systems (Oppermann & Simm, 1994) that could be integrated in a LMS is crucial (Graf, 2007; Leone, 2013).

Some researchers (Graf, Kinshuk & Ives, 2010; Limongelli, Sciarrone & Vaste, 2011) have successfully implemented adaptive plug-ins in Moodle 1.9, where adaptivity operates on the basis of the detection of students' learning styles by the Felder-Silverman learning styles model (FSLSM) (Felder & Silverman, 1988) as the most acknowledged model in this kind of applications. Explorative studies have been conducted on the use of artificial neural networks to increase the accuracy level of learning style identification (Bernard, Chang, Popescu, & Graf, 2015). Anyhow, no similar research experience seems to have been carried out with the latest versions of Moodle to date; besides, none of the adaptive plug-ins that have been analysed for this study has been adapted for Moodle 2.9 yet, nor it seems that learning formats that exploit the Moodle 2.9 conditional activities as an adaptive mechanism have been devised.

Recently several research projects funded by the European Union (EU) have been carried out

to provide networked and personalised learning environments for lifelong learners, but a few have investigated new applications that exploit Social Semantic Web to enhance LLL, like *Learning Technologies for Lifelong Learning* (LTfLL) (www.ltfill-project.org) and *Responsive Open Learning Environments* (ROLE) (Kroop, Mikroyannidis & Wolpers, 2015).

THE SSW4LL FORMAT

The *SSW4LL* format offers a learner-centred framework to back the characterisation of adult lifelong learners' PLEs through implicit and explicit tools of personalisation. The format is devised for adult lifelong learners in general, rather than for one specific cluster within, and for the expansion of all knowledge domains. Besides, the *SSW4LL* format supports mobile learning, but ubiquitous learning features (Leone & Leo, 2011) could be implemented as well, as an extension.

The synergy of formal and informal learning arises from the smooth integration of the different technological components, the light e-moderation of the learning environment by a facilitator, the support of a technical e-tutor and the continuous enrichment of the initial learning resources (formal environment) by social software and Social Semantic Web tools (informal environment).

The *SSW4LL* system, the technological architecture, is made up of Moodle 2.9 integrated with an adaptive mechanism (conditional activities), as the formal learning environment component, and of Semantic MediaWiki 2.3, Diigo and Google+, as Social Semantic Web tools and informal learning environment elements.

As a whole, the *SSW4LL* format offers an adaptive (Oppermann & Simm, 1994) modular, flexible and integrated architecture, compatible with future Moodle releases.

The format has been successfully implemented and validated by the course *SSW4LL2011* (Leone, 2013; 2014). Further experiences are in progress.

Needs Analysis, Paradigm, and Learning Strategies

In reference to the European framework of key competences for LLL (European Parliament and Council of the European Union, 2006) and to the results of the EU survey on adult education (AES) (European Commission, 2011), the *SSW4LL* format can contribute to: (1) learning to learn; (2) form active citizens, that is individuals who are engaged in the development of the multiple dimensions of citizenship, beyond knowledge towards the enhancement of competences and attitudes by experiencing active participation in different contexts; (3) support and deliver personalised and flexible learning; (4) facilitate learner-centred technology-enhanced learning; (5) promote inclusion; (6) improve digital and social skills.

The *SSW4LL* format is created to personalise learning in terms of self-organisation by adult lifelong learners working with the support of the facilitator, the adaptive mechanism, the technical eTutor and the peers (Leadbeater, 2004). In this format, personalisation aims to valorise learners' full potential and to empower individuals through knowledge sharing and co-construction. Learners are active co-designers of the learning experience (Maharey 2007). As a result, *learning work* turns into a *learning adventure* (Leo, Manganello & Chen, 2010), that is a learner-centred, holistic experience which involves a complex, continual, chaotic and co-creative process.

The theoretical background of *SSW4LL* draws on andragogy (Knowles, 1970) and socio-constructivism (Vygotsky, 1986; Varisco, 2002) theories. Learning is negotiated between the facilitator, the learners and the learning material, and expertise can be placed beyond the formal setting through learners' PLEs. The *SSW4LL* format can be developed through the following strategies:

- Brainstorming (in Moodle forums, and in Google+ by posts and hangouts);
- Problem solving;

- Collaborative and cooperative learning (in Moodle forums, Diigo and Semantic MediaWiki);
- Webquest (which includes cooperative work and problem solving);
- Reflection activities;
- Learning by doing;
- Self-learning, with the support of an adaptive mechanism in the formal learning environment (Moodle).

Technological Architecture: The SSW4LL System

The *SSW4LL* system is made up of integrated components of formal and informal learning environments.

Specifically, the design of the framework has been developed considering (Giovannella, 2008):

- The web used as an environment, where various tools and contents can be aggregated for the construction of a PLE;
- Open source, open content, open society and, therefore, adoption of open “machine-readable” standards;
- The learner's capability of managing his/her learning processes and of setting up his/her e-portfolio as aggregator of personal knowledge and competences (Lubesky, 2006).

The formal learning environment consists in Moodle 2.9, in which adaptive learning is enabled by its conditional activities. The elements of the informal learning environment are Semantic MediaWiki 2.3, Diigo and Google+, that allow adult lifelong learners for a qualitative different bottom-up approach to learning

By fully exploiting Moodle 2.9 adaptation features, that in the *SSW4LL* system are based on the detection of learners' learning styles (Felder & Silverman, 1988; Felder & Soloman, 1997), this LMS can deploy a personalised scaffolded learning

environment for self-regulated learners. Moreover, social software can be smoothly integrated in the architecture by Diigo widgets, by the GoogleLogin extension that allows Semantic MediaWiki users to login with their Google account, and by Moodle plug-in for Google+.

Formal Learning Environment: Moodle 2.9

All LMSs provide a wide range of features that teachers can exploit to create and deliver online courses. For this reason, they are commonly used by educational institutions to successfully offer technology-enhanced learning. All the same, LMSs normally do not consider learners' individual differences and supply very little or, in most cases, no adaptivity (Graf, 2007).

Additionally, the knowledge society and the LLL vision have required a large variety of skills to be developed in lifelong learners: the ability to locate and evaluate information effectively and efficiently; facility with making meaning by aligning new information with prior knowledge; and an ability to synthesise, critically analyse, and create new information within the context of larger social practices (Lin, 2011).

On the basis of these preliminary remarks, two relevant studies (Graf, 2007; Lin, 2011) and the author's prior direct experience have informed the choice of Moodle as the most suitable component for the formal learning environment in the *SSW4LL* system.

Furthermore, Moodle allows the implementation of different degrees of learning personalisation between the following extremes: (a) teachers can opt to roughly guide students, by scaffolding, and let them find their own way; (b) teachers can opt to give them a detailed map with checkpoints they must reach along the way, that is a more structured approach. Further, the determination of learners' learning styles is possible by creating a suitable quiz.

In the *SSW4LL* format, the abovementioned option (a) and the FSLSM (Felder & Silver-

man, 1988) are adopted to meet learners' needs and profiles, in accordance with the theoretical background of the format. Furthermore, several researchers concur on the validity of the FSLSM as the most appropriate to be used in adaptive learning systems (Graf, Kinshuk & Ives, 2010; Limongelli, Sciarrone & Vaste, 2011), as the *SSW4LL* system is.

Conditional activities aim to allow the educational designer to scaffold learners in accessing learning resources on the basis of one or more conditions. In the back end of the resources and activities (e.g., a forum) that the designer previously wishes to add to the course a *restrict availability* area is available for setting (e.g., on a date, on a grade, on the completion of an activity, etc).

The second element to make the learning environment adaptive is the *activity completion tracking* facility, which is the ability for users to mark tasks as "done" (by a tick) or to have tasks checked automatically by the system if the teacher chooses this option in the back end.

In the *SSW4LL* format a suitable and thorough combination of these conditions allows to produce different learning sequences, in which learning objects are proposed according to the students' learning profiles that are initially detected through an entry quiz.

Informal Learning Environment: Semantic MediaWiki, Diigo, and Google+

In the *SSW4LL* system the elements of the informal learning environment are Semantic MediaWiki, Diigo and Google+.

They have been selected among several alternative solutions on the basis of effectiveness and efficiency in relation to *SSW4LL* target learners' goals. Evaluation has been carried out on the following criteria, attributing a value on a 5-point Likert scale: social semantic features, effectiveness as tools for characterising adult lifelong learners' PLEs, novel features, possible integration with Moodle 2.9, easy-to-use interface and mobile

learning features. The categories of tools that needed to be considered for the *SSW4LL* system were aggregators, tools of semantic annotation, social bookmarking and recommended search, and social networks.

Organisation

Technical Competences Required

The implementation and management of the *SSW4LL* format requires the following professional profiles:

- A learning technologist, who has extensive knowledge of the use of Moodle, Semantic MediaWiki, Diigo and Google+, and of all the other technologies that could support learning and teaching within the *SSW4LL* format. He/she deals with the implementation, updating and troubleshooting of the different technological components of the format;
- An ICT technician, who has knowledge of a range of ICT hardware and applications commonly used, and has good problem-solving and organisational skills. He/she provides the facilitator and learners with technical support, guidance and maintenance in order to use all software/hardware correctly during the learning path;
- A (or more) teacher-facilitator, who is familiar with the design, implementation and management of Moodle courses, including the settings of conditional activities;
- Learners, who have basic digital competences and use of Web 2.0 tools (forums, wikis, social bookmarking and social networks).

Devices

The implementation of the *SSW4LL* format in a distributed learning environment requires an Internet connection and one of the following sets of equipment, according to the students' location:

- A workstation, a webcam and a headphone set if the students are in a fixed location;
- Smartphones or tablets if the students are in a mobile learning environment;
- Laptops, smartphones, ultra-mobile PCs or tablets together with the use of sensor network nodes, contact-less smart cards, RFID (Radio Frequency Identification) and QR (Quick Response) codes, if the students are in a ubiquitous learning environment (as an extension).

Evaluation and Assessment

The *SSW4LL* format is monitored through an entry and a final survey, and entry and formative self-assessment tests to evaluate its effectiveness in terms of participants' expectations and satisfaction, and achievement of learning goals, respectively. A final cooperative essay or project work provides summative assessment.

Recommendations for an Optimal Implementation

The format *SSW4LL* is very flexible for both the teacher-facilitator and the learners. Anyhow, essential elements for the success of the experience are: (1) thorough organization and management of the necessary hardware and software; (2) an adequate familiarisation of the learners with the learning environment (technology, tools and learning approach); (3) a light e-moderation by the facilitator, in order to provide a modulation of self-regulated and shared learning on the basis of the students' silent and/or expressed requests, with the aim of supporting participants' high motivation.

SWOT Analysis

Strengths of the *SSW4LL* format are scaffolded self-regulated learning, personalised and flexible learning, novel tools for the characterisation of adult lifelong learners' PLEs. Weaknesses are the initial technological issues that can origin

demotivation and disengagement. Opportunities are various: growing availability of open software and learning materials; increasing individuals' awareness of the importance of adopting a LLL vision. Vice-versa, possible threats are a teacher-centred approach, that could void the aims and flexibility of the format, and an insufficient Internet connection.

FUTURE RESEARCH DIRECTIONS

This research could open ways for advanced learning systems, which are able to meet learners' needs and characteristics, merge assets of formal and informal learning environments, and provide learners with dynamic personalisation of their PLEs.

In the future, improvements of the *SSW4LL* system include enabling the integration of additional social semantic tools to tackle differently knowledge management, syndicating resources and trustworthiness, that are actual research issues related to the enhancement of dynamic PLEs. Moreover, in-depth observation will be conducted in higher education on how the learning outcomes improve by transferring responsibility for the choice and configuration of the learning environment from the teacher to the learner by social semantic tools.

CONCLUSION

At the light of the fundamental technological and societal changes that have occurred in recent decades, current policies and research debate are focused on the development of disruptive education solutions on the basis of open, lifelong and ubiquitous learning frameworks. This change of vision is manifesting in a growing awareness that more personal, social and participatory approaches to learning are necessary to meet the lifelong learners' need to become co-producers

of their learning paths and to control the whole learning process.

The shift from formal to informal learning, from LMSs as organisation-centred spaces to PLEs as learner-centred spaces, can be turned into an integration of these two in a flexible and integrated learning environment.

This perspective manifests in a learning web where information is distributed across sites. As a result, knowledge management becomes an issue, and personalisation requires the support of adaptation and of semantics applied to social components (i.e., the Social Semantic Web).

The *SSW4LL* learning format has been devised to support the characterisation of adult lifelong learners' PLEs. The format offers an adaptive, modular, flexible and integrated architecture; the *SSW4LL* system is made up of components of formal (Moodle 2.9 with conditional activities as a suitable mechanism of learning adaptation) and informal learning environments (Semantic MediaWiki 2.3, Diigo and Google+). The format is compatible with future Moodle releases and easy to use for teachers-facilitators.

The influence of the informal learning components of the *SSW4LL* system is strong: where social software gives users freedom to choose their own processes and supports the collaboration of adult lifelong learners *anytime, anywhere*, Semantic Web technology gives the possibility to structure information for easy retrieval, reuse, and exchange between different systems and tools.

The format is conceived to empower adult lifelong learners by facilitating the acquisition of some of the skills necessary for the 21st century.

KEY TERMS AND DEFINITIONS

Adaptivity: In adaptive learning systems, it provides increased user's efficiency, effectiveness and satisfaction by greater correspondence between learner's needs and goals and the characteristics of the system.

Adult Education: All forms of non-vocational adult learning, whether of a formal, non-formal or informal nature.

Formal Learning: Hierarchically structured, chronologically graded educational system running from primary through to tertiary institutions.

Informal Learning: Unstructured learning that allows persons to acquire attitudes, values, skills and knowledge from daily experience, within the individual's environment (i.e., family, friends, peer groups, etc.).

Learning Management System: Organisation-centred learning space where online interaction takes place between learners and teachers.

Lifelong Learners: Self-regulated learners, characterized as demonstrating perseverance, initiative, and adaptive abilities. Self-regulation relates to an ability to recognize a need for further learning as well as to be proactive in gaining access to and accomplishing learning.

Lifelong Learning: A holistic vision of learning in different contexts (formal, non-formal and informal) and throughout life, based on the evolution of provider-driven education toward

personalised learning and aiming at improving knowledge, skills and competencies within a personal, civic, social and/or employment-related outlook.

Personal Learning Environment: A concept, a group of techniques and a variety of tools to (1) gather information, explore and develop relationships between pieces of information; (2) facilitate the access to and the aggregation, the configuration and the management of the individual's learning experiences. A PLE is an activity-based learning environment, user-managed and learner-centred; it is an open system, interconnected with other PLEs and with other external services.

Social Semantic Web: As a result of the merging of Social Web, the web of social relations and collective intelligence, and the Semantic web, the web of data, it consists in explicit and semantically rich knowledge representations created by social interactions on the Web.

Reflection as a Process From Theory to Practice

Sonia Bharwani

Indian School of Management and Entrepreneurship, India

Durgamohan Musunuri

Bhavan's Usha and Lakshmi Mittal Institute of Management, India

INTRODUCTION

Global boundaries, markets, customer demands, technologies, products, processes – all seem to be in a constant state of flux in today's dynamic business environment. There is considerable debate about the efficacy of the pedagogy used in developing and training management students to take on the mantle of being effective managers in this challenging and ever-changing business milieu (Boyatzis, Cowen & Kolb, 1995; Mintzberg, 2004; Raelin, 2009). Several researchers have critiqued that management education has become chain-bound by narrow vocationalism where functional and technical competencies are overemphasized at the cost of experiential learning which is an integral ingredient for the holistic development of a business manager (Reed & Anthony, 1992; Albert & Grzeda, 2015). It has been observed that management graduates often display analytical detachment and methodological elegance to the detriment of insight that comes from hands-on experience (Hayes & Abernathy, 1980; Inamdar & Roldan, 2013).

Researchers in the field of pedagogic practices like Hill (2003) and Raelin (2009) argued that learning by doing i.e. experiential learning where “concrete experience is the basis for observation and reflection” (Kolb, 1984, p.21) is really what managers need, to be effectual in today's dynamic business arena. There is a growing clamour for intersection of theory and practice in the field of management education and a shift in focus from

a teacher-centric approach to a student-centric, learning-focused approach. It has become imperative to address this issue by engaging in a deeper approach to learning. This can be done by laying emphasis on higher order thinking skills such as analysis, synthesis and evaluation which allow students to achieve enhanced levels of cognitive processing through transformative learning.

Thus, students of business management need to hone their cognitive abilities, learn from experiences and develop skills to question their mental models and underlying assumptions. This would enable them to develop new models and theories which are more relevant and *au courant* in terms of their current practice and thus, undergo transformative learning. Transformative learning is a deep-rooted, structural shift in basic foundations of thought, feelings, and actions (Mezirow, 1998). The pedagogical concepts of double loop learning, experiential learning and metacognition are important building blocks for attaining these transformative learning goals.

Double loop learning involves correction of errors by questioning the framework of learning systems and accordingly changing the governing values which underlie actions (Argyris, 2002). Experiential learning is based on the notion that experiences contribute to understanding and learning (Kolb, 1984) and metacognition (Flavell, 1979) involves thinking about one's own self and the attendant assumptions and mental images that underlie the thinking. A key aspect of transformative learning involves engaging in critical

reflection of one's experiences and the underlying assumptions which leads to a change in one's meaning schemes and perspectives (Mezirow, 1998). Thus, at the core of all of the above mentioned pedagogic concepts is the practice of reflection.

BACKGROUND

The Significance of Reflection

According Dewey (1933), an early pioneer of this precept, reflection can be defined as "active, persistent and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusion to which it tends" (p.9). Reflection as a process is meant to facilitate self-awareness in context of practice and encourage students to think critically. Further, reflection facilitates self-actualization and encourages the development of new knowledge and theory. In a dynamic environment where behaviour has to change on a continuous basis to adapt to the challenges of the situation at hand, reflection is "fodder for self-regulation" (Scott, 2010, p.432).

Daudelin (1996) defined reflection as "the process of stepping back from an experience to ponder, carefully and persistently, its meaning to the self through the development of inferences." Reflection is directly connected to learning since it aids students in drawing inferences from events and experiences which form the basis of future actions. Page & Meerabeau (2000) elaborated on this idea when they advocated for reflection because "various taken-for-granted elements of every day practice can be unearthed, made visible and considered for professional scrutiny."

Reflection, as such, refers to the practice of examining and analysing an experience, in the form of thought, feeling, or action, and ascribing meaning to it to glean its cognitive essence while it is happening or subsequently. Mezirow (1998) considered critical reflection as key instrument

by which one could question the validity of one's world views. He suggested three types of reflection based on their roles in transforming meaning schemes and perspectives: content reflection, process reflection, and premise reflection. The role of reflection in the students' learning cycle in transitioning from theory to practice and back to theory cannot be over-emphasized. Several researchers and academics have through their expositions clarified the meaning and utility of reflection in going beyond the surface approach to learning. Equally interesting is how practitioners i.e. teachers and teacher educators use the process of reflection to foster deep learning or life-long learning and improve teaching (Fry, Ketteridge & Marshall, 2009).

OBJECTIVES OF THE STUDY

Over the years, the education system in India has been following the surface approach to learning (Manikutty, 2010) which is typified by lecture-based classroom teaching, rote learning and an intention to merely complete the task at hand, with limited emphasis on critical thinking, active learning and collaborative learning. Cross-cultural studies comparing learning styles of students across countries show that in India, reflective practices and structured reflection are not widely prevalent concepts in mainstream professional education (Jaju, Kwak and Zinkhan, 2002) which could be attributed to the country's collectivist culture with a high degree of power distance and authority acceptance (Manikutty, Anuradha & Hansen, 2007). Hence, there is almost no research about the use and the efficacy of reflection as a learning tool in the context of Indian management education. This research paper endeavours to bridge this research gap by mapping the Indian management students' perception of reflection and the value they place on reflection as an instrument of learning and continuous development in their professional and personal pursuits.

FOCUS GROUP STUDY

One way of gaining powerful research insights within social science fields such as education and healthcare are focus group interviews which are usually grounded in a qualitative paradigm. Focus groups are “designed to obtain perceptions on a defined area of interest in a permissive, non-threatening environment” (Krueger, 1994, p.6) by encouraging open conversation and debate among the research participants to gather an in-depth understanding of their reality in terms of their knowledge and experiences.

This methodology provides an emic perspective or an insider’s view and uses inductive processes to analyse and interpret participants’ opinions and views. Focus group interviews were chosen over individual interviews keeping in mind that “the dynamic interaction afforded by focus groups enables the eliciting of a diversity of views from participants and the immediate clarification of issues that affect this diversity” (Hollis, Openshaw & Goble, 2002, p.4). The study, thus, used a qualitative approach by conducting focus group interviews to present the student participants with a forum to air opinions. It aimed at understanding students’ perceptions and interpretations of use reflection and reflective practices as a learning pedagogy without subjecting them to the pressure of arriving at a consensus.

Participants

Participants for the focus group study, which was conducted in May 2013, were chosen from among the undergraduate students of a hospitality and business management institute situated in Gurgaon, India. The institute had been conducting the undergraduate degree programmes of a well-established, U.K.-based university in India for more than a decade. The course curriculum of the university actively incorporated and used reflection and reflective practices in the pedagogy adopted.

The selection of the research participants was made keeping in mind the students’ exposure to and familiarity with the concepts and the practice of reflection as part of their course curriculum. Three focus group interviews were conducted in the same week. It was decided to restrict the number of participants in each focus group to a maximum of 7 students. Three different cohorts were chosen from each of the two undergraduate programmes, B.Sc. in Hospitality Management and B.B.A. (Hons.) in Business Management programme for the three focus group interviews. Focus Groups A and B comprised of students in the Final Years of the Hospitality Management and Business Management programmes, respectively. Focus Group C was selected from the Second Year students of the Business Management programme.

For Focus Group A, seven students were selected using convenience sampling from volunteers from the Final Year Cohort of the Hospitality Management programme. The selection was done on the basis of computer-generated random numbers. The group comprised of 3 female students and 4 male students. In a similar manner for Focus Group B, six students were selected from the Final Year Cohort of the Business Management programme and another six students were selected from the Year 2 Cohort of the Business Management programme for Focus Group C. Both the latter groups comprised of 4 female students and 2 male students. These ratios of male and female participants were representative of the gender profiles of the respective cohorts.

Procedure

The focus group studies were conducted within broad parameters outlined by Krueger (1994) with the help of question routes which were developed using protocols and strategies enunciated by him. Each focus group was of an average duration of 45 minutes. A series of introductory, transitional, key, probing and closing questions, as outlined in Table 1 in Appendix 1, were framed and phrased

in a conversational format to gather richer details about the participants' experiences with reflective practices. Dichotomous questions and questions which required students to make non-contextual judgments were avoided (Hollis et al., 2002).

At the outset of the focus group, the participants were apprised of the purpose of the interaction which was to understand students' perceptions and viewpoints regarding reflection and reflective practices. Basic rules for the interaction were defined and it was emphasized that there was no pressure for consensus. For each of the focus group session one of the researchers (SB) played the role of the moderator to facilitate group interaction. The second researcher (DM) played the role of an independent observer and took field notes of significant comments while observing and analysing the group dynamics. The entire proceedings of each of the focus groups were video-recorded and then transcribed. Immediately after each session, the moderator and observer conducted a debriefing session in order to facilitate later analysis.

DATA ANALYSIS AND FINDINGS

The transcripts of the video recordings were minutely examined and coded to align common concepts and significant themes together. This facilitated thematic analysis of the findings from the three focus group interviews. The observer's notes were used concurrently with the transcripts to identify the emerging categories in the theme of reflection from the proceedings of the focus groups. These were as follows:

- Perception of Reflection
- Practice of Reflection
- Experience of Reflection
- Benefits of Reflection
- Factors Enhancing and Inhibiting Reflection

Perception of Reflection

Students across all three cohorts viewed reflection as a tool for self-analysis and evaluation, learning from their experiences and course-correcting in the future in case of deviant outcomes. Words such as 'introspection', 'contemplation', 'flashback', 'self-criticism', 'self-evaluation', 'self-analysis', 'self-monitoring' and 'questioning one's assumptions' were used by the students while enunciating the meaning of reflection. A common theme which emerged was that reflection could be perceived as a process of revisiting one's own experiences to understand them better and 'learn from one's own mistakes and those of others' so that future experiences and decision can be informed. Another important element discussed in Groups A and B which comprised of Final Year students from both disciplines, included making connections between existing knowledge and newly acquired knowledge to integrate and enhance understanding for better guiding future action.

There was high degree of congruence between the students' perception of reflection and the definitions and descriptions of reflection found in academic literature. According to Rodgers (2002) reflection is a 'meaning-making' process. It is a practice which helps convert raw experience into intelligible theory grounded in concrete experience and supported by existing theoretical concepts. It forms the foundation of intelligent actions which are deliberated upon (rather than impulsive). Intelligent actions find their origins in information garnered from experience and are driven by one's final goals. But undergoing an 'experience' is not the only sufficient condition for reflection since experience is not primarily cognitive (Dewey, 1944). What is equally important is thoughtful consideration of the experience to accord meaning to it and give it value. Thus, it is essential to develop "the ability to perceive and then weave meaning among the threads of experience" (Rodgers, 2002, p.847- 848).

Practice of Reflection

In discussing the practice of reflection, students identified different ways in which they indulged in reflective practices. In the academic context writing reflective statements, maintaining reflective diaries and journals and keeping portfolios were identified as the most commonly used methods of structured reflection. They adeptly identified modules in their curriculum where reflection was an actively used pedagogy. Besides writing reflective expositions, ‘thinking’, ‘contemplating’, ‘voicing one’s thought’, and ‘sharing one’s views’ were also described as ways of reflecting used by students in the academic context.

Students across all three focus groups used the terms ‘mulling over’, ‘ruminating’ and ‘musing’ while describing reflecting in a personal, non-academic domain. These terms were used to describe reflection in isolation of others, in an unstructured manner when students were simply ‘revisiting’ their personal experiences for the purpose of introspection and self-analysis. However, some students of Focus Group A stated that while they did reflect in isolation, they believed that ‘sharing reflections’ with friends and mentors and using others as ‘sounding boards’ may enhance the quality of the ‘take-aways’ or learnings from the reflection. Another interesting revelation by this group was the increasing use of social media like Facebook (status updates) and Twitter as well as personal blogs for reflection by voicing their thoughts and airing their opinions on-line and also revisiting their ‘older posts’ to analyse their earlier thought processes.

Le Cornu’s (2009) model of reflection which advocated that individuals reconstruct and reflect on assimilated knowledge by thinking, speaking and writing, corroborates with the students’ views. While thinking about an experience is the first step in reflection, by itself it may not prove to be adequately sufficient for the task. External articulation in the form of speech or writing may be required “in order for individuals to consolidate and concretize their thinking” (Le Cornu, 2009,

p.282). Further, Rodgers (2002) also contended that reflection is a collaborative process and needs to happen in interaction with others. Reflection can be done in solitude, but reflection in community facilitates a broader understanding of an experience in the learner. Use of social networking sites (SNS) for reflective learning enhances student engagement by providing them with a platform for individual expression as well as collaborative connection (Park & Son, 2011). The findings from the focus group studies supported these premises as discussed above.

Experiences with Reflection

While discussing their experiences with reflection Focus Group A described their initiation to structured reflection in the course of their Hotel Operations module which required them to train in practical skills for restaurant, kitchen and front office operations. The students were required to maintain a reflective diary about their practical experiences on the shop floor and analyse their performance on a regular basis. They discussed the importance of maintaining a written record as an aid to ‘reflecting-on-action’ (thinking retrospectively on practice) since they had limited experience and skills in ‘reflecting-in-practice’ (thinking that shapes practice during practice) (Schön, 1987).

Both Focus Group A and B were appreciative of the role of the reflective portfolio that they were required to maintain during their year-long industry internship, in enhancing the learning take-aways from their practical experiences. Focus Group C, being academically junior, had still not been exposed to subject modules which used reflective practices to the extent that their seniors had and hence were unable to value-add to the discussion. All the focus groups concurred that for the uninitiated, maintaining a reflective log can be ‘a tedious activity’ and ‘a chore.’ However, they conceded that the process becomes less tiresome and even a positively viewed activity with increased familiarity and repetition.

In response to the query of whether the students had the opportunity to reflect in a structured manner or indulged in practices which could be construed as reflection prior to undertaking their undergraduate studies, the majority of the students across the focus groups answered in the negative. A couple of exceptions were students who had done their schooling in Australia and Canada and thus had engaged in reflective practices even at the school level. On probing further, some of the students who had done their schooling within India recalled instances where they wrote a 'summer vacation diary' or had a teacher-led in-class reflective discussion or were required to write essays which had an element of self-analysis and meaning-making.

The students' perception regarding the practice of reflection as discussed above correlates with Rodgers' (2002) contention that reflection is a distinct, rigorous and disciplined way of thinking. According to her, reflection is more than haphazard 'mulling over' something. As a process it finds its roots in scientific inquiry and is made up of structured and precise steps which include observation and description of experience, analysis of experience in terms of generation of explanations and development of theories, followed by intelligent action and active experimentation.

Benefits of Reflection

In process of discussing why students reflect, the students' perceptions of the benefits of reflection were identified. 'Self-awareness', 'knowing one's strength and weaknesses', 'betterment through experience', 'mental clarity', 'reassurance from peers' and 'validation of one's thought processes and actions by others' were some of the key themes identified.

According to the focus group findings, the meta-knowledge gained through the process of reflection made the students more confident and self-aware and contributed to their emotional intelligence quotient. It also brought about a 'change in attitudes' and inculcated 'independent thinking'. To quote a participant from Focus Group A, 'I

understood the mistakes I did, wrote them down to see how I could rectify and work around them and be a better leader. The process enhanced my learning curve. You don't make the same fundamental mistakes the next time over.' Students undertook unstructured reflection to analyse and understand their experiences especially 'when things had gone wrong'. Thus, the role of reflection in helping a learner move from the state of disequilibrium or disturbed perplexity to a harmonious state of understanding was highlighted during the focus group discussions. Literature also highlights the important outcome of this process of exploration and internal scrutiny as transformative learning through changing of one's perspective as new information and experiences are encountered (Peltier, Hay & Drago, 2005).

Factors Enhancing and Inhibiting Reflection

The focus group discussions also focused on the factors that facilitated and enhanced reflective processes and practices among the participants and inhibiting factors for reflection. The students identified collaborative environment, personal disposition and time as the key factors that bolstered reflective practices. 'You reflect when you want to do better in life' and 'the college environment, faculty members, family and friends encourage one to reflect' were some of the opinions voiced by Focus Group A. Their contention is supported by Bulpitt & Martin (2005) who summed up the conditions necessary for reflection as "support, time and space and a collaborative environment" (p.208). Further, Le Cornu (2009), too, highlighted the role of a "respectful, receptive ear" in encouraging dialogue and fostering reflection.

While identifying the constraining factors, Focus Group C was vocal in enunciating that 'you need to courage to do it' since deep critical self-reflection can be uncomfortable process requiring the reflector 'face the honest truth'. Lack of time and opportunities for structured reflection along with poorly developed reflective skills were also

identified as impediments to reflection by Focus Group B. The students' perception in this context were on similar lines with Boud & Walker's (1993) research which has identified internal barriers in terms of preparedness and intent and external barriers such as support systems and inadequate preparedness which impact upon the ability of the learners to engage in reflective practices.

Table 2 in Appendix 2 summarises the findings of the focus group study based on the various themes related to reflection.

DISCUSSION

The aim of the study is to throw light on the practice of reflection as understood by students pursuing mainstream professional education courses in India. Reflection brings unconscious and implicit thinking and understanding to an explicit level. It refers to the cognitive ability to examine the dissonance of personal experiences in the context of one's prior thoughts and assumptions. It is a meaning-making process which entails a quest for alternative explanations and interpretations in order to reconcile ambiguity and inconsistency between one's experiences, actions and assumptions, and thus, fosters transformative learning.

Research showed that the students from the final year cohorts of both the curriculum streams who had more experience in practicing reflection had a better grasp of the concept and practice of reflection and were more comfortable in engaging with reflection for their personal as well as professional growth. Focus Group C which was selected from the Year 2 cohort which had comparatively lower exposure to structured reflective practices had limited understanding and found reflection to be a 'difficult' and 'not so comfortable' practice.

Another important finding which emerged was the students perceived that reflection was more a collaborative process rather than an independent, individual process. Rodgers (2002), too, advocated the need for and the benefits of collaborative reflection as under:

- It leads to the affirmation of the value of one's own experience which otherwise may have been summarily dismissed as 'unimportant'.
- It helps in seeing matters in a new light when others offer their perspective and help in broadening the realm of understanding.
- It supports the process of inquiry (which might be difficult to sustain alone) by making the learner responsible and accountable to a group.

This highlights the importance of role of the teacher in encouraging and developing the students' reflective skills and supporting them by providing a collaborative environment to practice reflection. In addition, there is an increasing use of social media such Facebook and Twitter as well as personal online blogs by students to externally articulate reflections.

The focus groups perceived that personal dispositional factors played an important role in encouraging reflective behaviour. Reflection requires an attitude that values one's own personal and intellectual growth and that of others. Along with cognitive discipline, reflection also requires emotional discipline on part of the individual to objectively accept and analyse what evidence indicates. To gain the maximum from reflective practices in terms of personal and intellectual growth, reflection should be ideally guided by a basic attitude of single-mindedness to engage in the experience in an undistracted manner. Further, open-mindedness is also essential to entertain many interpretations of the experience. This allows one to gain a broad and varied understanding of one's response and the actions that flow from it, rather than cling doggedly to preconceived notions. Lastly, one must be grounded in reality and question the real-life implications of the understanding gathered through reflection. This requires acknowledging that a shift in understanding of an experience may result in a paradigm shift in outlook.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

The sample for the research was a non-probability one, since the participants for the focus groups were chosen from among volunteers and volunteers by their very nature preclude randomness. Since both the researchers were familiar with the participants by virtue of being faculty members at the institute, the focus groups were formed by selecting from among the volunteers on the basis of randomly generated computer-assigned numbers to eliminate bias in selection.

Another limitation that stems from the sample relates to its size which was limited to a maximum of 7 participants in each focus group. While the sample size is small in absolute terms, in relation to the average cohort size of 30 students at the institute it was considered a fair representative of the internal population who practice reflection. However, the study being a focus group study, by its very nature limits external validity and the generalisability of its results to a larger population. However, in context of the research objectives, the sample size was considered to be adequate for the purpose of the research which was preliminary in nature. Further, in order to maintain consistency, similar questioning routes were used in all focus groups with the same researchers playing the roles of moderator and observer respectively.

The preliminary findings discussed above contribute to understanding the Indian students' perspective on the utility of reflection in going beyond the surface approach to learning and transcending from theory to practice. However, further quantitative research which would help generalise these preliminary findings to a broader population and make a case for introducing and actively using this learning tool in management education in the Indian context, is required.

CONCLUSION

If we recognize and accept that to be effectual in today's dynamic business environment students

will have to deal with complex problem solving on a regular basis, it is then critical that they develop skills to engage in reflective practice. Reflection will enable student practitioners to distil meaning from their experiences and apply the essence of the learning to the establishment or evolution of processes in the complex organisational context, thus enabling them to synergise theory and practice.

Since reflective thinking is not necessarily an innate trait, the teacher or educational instructor plays a key role in creating a learning environment in which reflective practices are facilitated. Such an environment encourages open discussion, allows for questioning of established paradigms and voicing of divergent views and enables learning to transcend beyond the surface approach. Thus, for reflective learning to flourish, the teacher should be regarded by the learners as a mentor and a coach who promotes learning by engendering a non-threatening learning environment by encouraging questions and open discussions. Clearly, the role of the teacher in nurturing reflection and reflective practices among students cannot be undermined.

A deeper understanding of the meaning, utility and the criteria for inculcating reflective practices is one of the key ingredients for academic success and plays a vital role in elevating the educational experience of learners. Using active pedagogy which allows for observing and reflecting on experiences creates learning that involves "challenging assumptions, seeking alternatives, identifying areas for improvement... (and) shows active and conscious engagement, characteristics commonly associated with a deep approach to learning." (Peltier et al., 2005).

To sum up, it can be held that reflection plays a crucial role in creating meaning out of experiences in an iterative forward-moving crescendo of learning, alternating between practice and theory. Further, the criticality of the role of an instructor in fostering high order reflective and transformative learning cannot be over-emphasised.

KEY TERMS AND DEFINITIONS

Deep Learning: Learning based on critical examination and understanding of new facts, theories and concepts by linking them with existing cognitive structures and knowledge.

Experiential Learning: A process through which knowledge, skills and attitudes are developed through direct experiences that are supported by reflection, critical analysis and synthesis.

Metacognition: Self-monitoring one's own thought processes and the attendant assumptions that underlie the thinking.

Reflection: The practice of examining and analysing an experience to glean its cognitive essence in order to foster deep or life-long learning.

Surface Learning: Learning based on fact memorisation and lower level cognitive abilities.

Transformative Learning: Learning that brings about a change of perspective in the learner.

APPENDIX 1

C

Table 1. Question route for focus group interviews

Opening address Statement of purpose of the focus group session and the mechanics of the process. Emphasis on 'no pressure for consensus' to put participants at ease. Students were also assured of the confidentiality of their responses. Introductory question How do you interpret and understand the terms 'reflection' and 'reflective practice'? Key questions Why do you reflect? What factors encourage you to reflect? What are the impediments to the process of reflection? Transitional questions Before joining this institute and following the U.K. University curriculum have you ever reflected in a structured manner or indulged in practices which could be construed as reflection? Can you describe any of your experiences with reflection? Key questions In what ways can you reflect? Do you reflect in isolation or share your reflections with others? Probing questions Do you reflect in the academic context alone? Closing questions Any other thoughts about 'reflection'? Is there anything else that you feel may have been overlooked?

APPENDIX 2

Table 2. Thematic analysis of the findings of the focus group study

Themes of the Study	Findings
Perception of Reflection	• Tool for introspection, self-analysis and evaluation of experiences • Meaning-making process which serves as a guide to future action
Practice of Reflection	• Reflection can be practiced in isolation but works more effectively as a collaborative process • External articulation helps consolidate and concretize reflective thoughts • Social media such as Facebook, Twitter and on-line blogs have emerged as popular tools for external articulation and collaborative reflection
Experience with Reflection	• Increased familiarity and exposure to reflective practices improves perceived utility of reflection and reduces associated tedium. • Limited use of reflection as a pedagogical tool in mainstream education in India
Benefits of Reflection	• Helps change attitude and perceptions based on analysis of experiences • Enhances learning curve and leads to personal and intellectual growth • Increases self-awareness, confidence and emotional intelligence
Factors Enhancing and Inhibiting Reflection	• Enhancing Factors: Personal disposition, open-mindedness, collaborative environment and time • Inhibiting Factors: Lack of time, mental unpreparedness and lack of support systems conducive to reflective practices

Relationship Among Intelligence, Achievement Motivation, Type of School, and Academic Performance of Kenyan Urban Primary School Pupils

Jessina Mukomunene Muthee
Kenyatta University, Kenya

Catherine G. Murungi
Kenyatta University, Kenya

INTRODUCTION

In Kenya and many other countries examinations have been accepted as an important part of the education system. Examinations have also been used as basis for judging students ability and means of selection for educational advancement and employment.

Background

Every year thousands of Kenyan pupils sit for the Kenya certificate of primary education (K.C.P.E.) examinations. This is an examination done at the conclusion of eight years of learning in primary school. In spite of learners being exposed to the same environment, uniform program of classroom instruction and some may even possess similar IQ'S, discrepancies in academic performance have been observed to arise every year. Private schools albeit the high cost ones have attained high scores in Kenya certificate of primary education and contributed to nearly 80% of form- one students in national schools.

Extensive literature survey on academic performance of primary school showed that very few studies addressed the relationship between psycho-social factors and academic performance in Kenyan context. Most of the available literature reviewed comprise of studies done in western

countries and small proportion from India. Studies in Kenyan setting are fewer in comparison to efforts made abroad. The present study attempted to explore the nature and degree of relationship between academic performance and selected psychosocial variables such as intelligence, type of school and achievement motivation.

Cognitive abilities are widely regarded as a key component of intelligence which is a concept that is difficult to define (Hucken burry and Hucken Burry, 1997). It has been said that there are probably as many definitions of intelligence as there are experts who study it. Simply put however intelligence is the biological substrate of mental ability, the brains neuroanatomy and physiology, the manifestation of intelligence, the level of performance on psychometric tests of cognitive ability (Gardner, 1993).

Numerous researches have been done in western countries on the relationship between intelligence and academic performance (Vygotsky, 1978; Brody 1997; Ceci & Williams 1997; Ediseth, 2002, Parker et al; 2004) and these researches seem to agree that there exists a relationship between intelligence and academic performance and that higher educational achievement is predictive of higher intellectual outcomes.

Intelligence as measured by the Raven's standard progressive matrices has been found to be the best predictor of student's grade point average

(GPA) in all grades (Laidra et al; 2007). Deary et al; (2007). Also found a strong and positive relationship between intelligence and academic achievement. This study examined between psychometric intelligence at age 11 years and education achievement in 25 academic subjects at age 16. The trait and a latent trait of education achievement were 0.81. General intelligence contributed to success on all 25 academic subjects.

Direct relationship between intelligence and academic performance has also been reported. (Gagne & Stpere, 2002; Kossowska, 1999; Smith & Dobbs, 1999). In addition some researcher's view intelligence and academic achievement as identical constructs. Others assert that intelligence is causally related to academic achievement of success in academic work (Laidra, Pull mann & Allik, 2007).

Academic achievement motivation has been defined as learners need or drive towards the achievement of success in academic work (Amalaha, 1975). Motivation affects people's lives every day. People are motivated to engage in academic tasks if they value the task and if they expect to succeed at a task (Eccless, 1993, and Eccless & Wigfield, 1992).

It has been observed that many factors promote or hinder the success of students in educational institutions. Among them are achievement motivation and satisfaction with school experiences (Lampart, 1993). A great deal of research has also revealed that students of high academic motivation are more likely to have increased levels of academic achievement and lower school dropout rates (Blank, 1997).

Other studies have also reported positive relationship between motivation and academic performance (Johnson, 1996, Sandra, 2002; Brouard and Garrison 2004; and Skaalvik, 2004, 2006).

Literature evaluating the effects of school type on academic performance has grown rapidly over the past decade. For example the impact of Catholic schools (Private) on academic performance has received considerable attention in USA.

Good school facilities which are mostly found in private schools are observed to support educational enterprises. Research evidence abound (Cash, 1993; Earthman and Lemaster, 1996; Lemaster, 1997; Lackney, 1999; Cotton, 2001; and Schneider, 2002) that clean air, good light, small quiet comfortable and safe environment are important for good academic performance. Schools that have poor conditions because of factors such as overcrowding, differed maintenance or poor designs signal poor operating practices and hence poor academic performance. Such schools are mostly identified among public sector.

High school type appears to be strongly associated with educational outcomes (Checci et al; 1999). Boero et al; (2001) also confirms the importance of high school type for academic performance using his study sample of Italian college graduates that showed that the final graduation mark dropped significantly when one compared general (public) and private schools graduates. Private schools seemed to do better.

Evans and Schwab (1995) report a study on the effects of Catholic schools on high school completion and college enrolment probability. They also highlighted the endogeneity issues that can arise from self selection of students into Catholic schools and used instrumental variables to identify the effects of Catholic schools attendance on measures of academic success. They concluded that catholic schools raise subsequent educational outcomes. The Catholic schools in this case represented private schools.

Although many studies are in favour of private schools doing better in academic performance as compared to public schools, other studies also seem to differ with the idea. For example, Bertola & Cheddi (2002), Studied a sample of University students from the University of Millan. Their study revealed that those coming from general (public) schools scored better than otherwise comparable students on a range of performance indicators. They also considered the differences in academic performance between public and private schools students, finding that public schools were associ-

ated to better performance followed by religious private schools and lay private schools.

Hypothesis

The study was designed to test the tenability of the following Hypotheses:

1. There is a significant relationship among intelligence, achievement motivation, school type and academic performance.
2. Pupils of private and public schools differ significantly in (a) academic performance, (b) intelligence and (c) Achievement motivation.

Method

Sample: The subjects of study comprised 200 (101 boys and 99 girls) standard eight pupils from Nairobi city primary schools. The stratified random sampling technique was used to have private and public school representation. Their age ranged from 12 and 14.5years.

Measures

1. **Raven's Standard Progressive Matrices (SPM: Raven, 1939):** This was used as a screening test of cognitive ability. The test is designed to measure a person's ability to form perceptual relations and to reason by analogy independent of language and formal schooling and may be used with person ranging from six years old to adulthood. The candidate is provided with multiple choices to identify the missing segment required to complete a larger pattern in each test item. In this study, the test was administered in groups under the supervision of trained research assistants and the role scores were converted to percentile scores for analysis. The test was selected as it eliminates the bias of language. Total scores indicate an individual's intellectual capacity regardless of his/her level of education.

2. **Measure of Academic Performance:** The overall marks obtained by pupils in the class examination of various subjects were collected from school records. The scores were then converted into percentages and were used as indices for academic performance.
3. **Achievement Motivation Inventory (Muthee & Thomas, 2009):** This is a 32 item scale intended to assess the achievement motivation levels among students. Cronbach alpha computed for the scale was found to be 0.749 indicating that the scale has satisfactory internal consistency reliability. Validity for the scale is claimed on the basis of the fact that it is modeled after well known inventories meant for measuring achievement motivation. The scoring of the scale is done in such a manner that high scores indicate high levels of achievement motivation.

Statistical Techniques

The major statistical techniques used for analysis of data were t- tests and multiple regressions. The results obtained using these techniques are detailed below. Mean scores on different study variables obtained by students belonging to private and public schools were analyzed using t – testes. The results obtained are presented in Table 1.

In Table 1, the results of t – tests indicate that the students of private schools differ significantly from students of public schools in terms of academic achievement, and intelligence but not in terms of achievement motivation.

An examination of details of scores obtained by the sub groups indicate that private school students obtained greater means scores in academic achievement (71.22) and intelligence (mean percentile =76.57) and when compared to scores obtained by public school students (60.26% and percentile of 60.24 respectively).

The findings in the present study are in agreement with those of Boyle (1962) who examined the effects of differences in quality high schools

Table 1. Differences based on type of school

Variables	Type of School	N	Mean	Std. Deviation	t-values	Sig.
Academic achievement	Private	100	71.22	11.68836	5.884	.000
	Public	100	60.26	14.50226		
intelligence	Private	100	76.57	19.54665	4.867	.000
	Public	100	60.24	27.25607		
Achievement motivation	Private	100	125.18	13.67988	-1.108	.269
	Public	100	123.01	14.01694		

in Western Canada. His findings revealed that students who attend good quality schools has higher educational aspirations and expectations and hence perform better.

One explanation that may be offered for the present finding is that those who are studying in better schools are already a select group who can be expected to be above average in many respects including intellectual ability. In such a case, it may be not surprising that their achievement is also superior to those studying in schools with less facility.

From Table 2 it can be seen that among the variables considered for the study, intelligence was the first and the most important variable to enter the regression equation. The multiple R of intelligence is 0.593 and the R^2 is 0.352. This means that intelligence alone accounts for 35.2 percent of variance in academic performance of the students. The beta value associated with intelligence is 0.445. The positive sign of beta value indicates that there is a positive correlation between intelligence and academic performance.

Achievement motivation was the second variable which entered into the regression equation for prediction of academic achievement. With the addition of this variable, the multiple R improved to 0.655 and R. square became 0.429. The change in R square was 0.076. This meant that achievement motivation accounted for an additional 7.6 percent of variance in academic achievement. Intelligence and achievement motivation in combination could predict 42.8 percent of variance in academic achievement. The beta value for the achievement motivation was 0.282 which indicated positive relation between achievement motivation and academic achievement.

Table 3 describes the third and final variable which entered into regression equation for prediction of academic achievement was type of school. the beta value for school type was 0.208 which indicated a positive relation between type of school and academic achievement. With the additional of this variable the multiple R became 0.683. The change in R squares was 0.038. This showed that school type together could account for 46.6%variance in academic performance.

Table 2. Relative contribution of the Independent variables to the prediction

Predictors	Unstandardized Coefficients		Standardized Coefficients			Multiple Correlations		
	B	Std. Error	Beta	t	Sig.	R	R ²	R ² Change
Constant	3.259	7.174		.454	.650			
Intelligence	.253	.034	.445	7.503	.000	.593	.352	.352
Achievement motivation	.293	.058	.282	5.042	.000	.655	.429	.076
Type of school	5.962	1.649	.208	3.615	.000	.683	.466	.038

Table 3. List of variables which got excluded from the final regression equation

Variable	Beta in	t	Sig
Gender of the child	-.90°	1.679	.095
No. of brothers	-.013°	-.236	.813
No. of sisters	-.003°	-.058	.953
Living with	-.048°	-.875	.383
Education of the father	.081°	1.176	.241
Education of the mother	-.037°	.519	.605
Monthly income	.116°	1.564	.119
Occupational status of father	.088°	1.474	.142
Occupational status of mother	-.036°	-.615	.540
Socio economic status T.score	.016°	.205	.838
Class climate	-.036°	-.641	.522
Home environment	-.004°	-.078	.938

The multiple correlation of 0.683 which amounts to an explained variance of 46.6% shall be considered sizeable, in view of the fact that only 3 variables are involved in the equation. Among these three variables the most important one is intelligence which alone accounts for 35.2% of the explained variance. The finding is understandable and agrees with the common sense notion that the major part of one's academic achievement is determined by one's intellectual potential. The results obtained are also in consonance with the work of several earlier researchers (e.g. Vygotsky, 1978, Brody, 1997, Ceci & Williams, 1997; Cronbach, 1949).

Of greater interest and significance is the finding that achievement motivation, which is a non-cognitive variable, has a role in academic achievement that is over and above the role played by one's cognitive potentiality. This implies that significant improvement can be made in achievement of a student by optimizing his or her motivational level. Findings similar to the present one have been reported by Johnson 1996; Broussard and Garrison, (2004).

With regard to the variable type of school, the results obtained in the present analysis imply that being in a private school is a predictor of higher academic achievement when compared to be-

ing in a public school. This finding is of special significance in the context of Kenyan society. Where private schools in the private sector provide better facilities for students and are well staffed when compared to schools in the public sector. Summarizing these findings, multiple regression analysis reveal that better academic achievement among standard eight pupils in Nairobi, Kenya is predicted by higher levels of IQ, higher academic motivation and being placed in private schools for studying.

FUTURE RESEARCH DIRECTIONS

A similar study may be conducted on predictors of academic performance and motivation in primary schools of rural areas to cross check whether the conclusions arrived at in the present study which was conducted on urban setting, could be generalised.

The present study concentrated on correlates of academic achievement and motivation among adolescents in primary schools. There is need to examine the factors which influence academic performance and motivation in higher education among post adolescent learners.

Personality variables should be also taken up besides school variables and home environment variables in order to get more comprehensive picture of the variables affecting academic achievement and motivation.

CONCLUSION

The association found between various psychosocial variables viz., achievement motivation, type of school level of intelligence with academic achievement, revealed in the present study have lent some additional support to the findings of earlier studies.

The study helped to generate empirical support to the contention that both cognitive factors (intelligence) and non cognitive factors e.g., motivational and environment are equally important in determining academic performance of students.

The importance of achievement motivation as a predictor of academic achievement, revealed in the present study, as well as the identification of the significant predictors of achievement motivation has important implications for both educators and parents. Motivation being a non cognitive trait, amenable to modification through training, one may attempt to improve the motivational level of learners in order to bring positive results in academic performance.

From the finding the impact of type of school on academic achievement, implies that the school atmosphere, determined by various factors like facilities available, quality of teaching, evaluation, accountability and discipline maintained, etc., has some relevance in academic achievement of students. It is hoped that these findings shall be given serious attention by school administrators and governmental authorities and initiate positive changes in the administrative and academic set up of schools.

KEY TERMS AND DEFINITIONS

Academic Performance: As used in the contest of this chapter, the expression academic performance refers to the percentage of marks obtained by the pupils on each of the five compulsory subjects after two terms of study in standard eight class. The overall percentage on five subjects

was calculated from this information. Information forms containing columns to enter total marks obtained by the students and the maximum marks on each of the five compulsory subjects were used for the purpose. This information was provided by the school authorities.

Intelligence: The term ‘intelligence’ as used in the context of the present study refers to cognitive abilities. This construct was operationalised using standard progressive matrices, which was developed by Raven’s (1938) to test people’s ability for observation and clear thinking. It measures a person’s ability to form perceptual relations and to reason by analogy. The test can be administered to any individual in the age range of 6 years and above irrespective of language and schooling. The total score indicates an individual’s intellectual capacity regardless of his or her level of education.

Motivation: The expression ‘motivation’ in the present study refers to the persons aroused desire for participation in the learning process and perform at high level of competence. This construct was operationalised using an achievement motivation inventory constructed by the present investigators (Muthee, murungi and Thomas, 2009) The tool measured four different aspects related to academic motivation, viz., ⁽¹⁾ motivation for achievement ⁽²⁾ inner resources of the learner ⁽³⁾ interpersonal strengths in learners and ⁽⁴⁾ work habits.

Type of School: In Kenya there are two types of schools. The government sponsored schools (public schools) and the private owned schools (private schools). In this study both public and private primary schools participated in the study. Primary school level: this is the elementary level school, it houses pupils of ages ranging from seven to sixteen years. In this study pupil’s in the age range of eleven years to fourteen under half years participated in the study. These learners are expected to be in standard eight class in Kenyan primary schools.

Screencasts and Learning Styles

Rui Alberto Jesus

CESPU, Instituto de Investigação e Formação Avançada em Ciências e Tecnologias da Saúde, Portugal

INTRODUCTION

Many people have heard about learning styles. Besides the criticism about the instruments that detect and classify these preferred learning modalities, learning styles appear to explain something that is obvious: people learn in different ways.

In broader terms, people have different personalities, different ways of processing information, and different sensory preferred modes (among others factors), that influence how each person relates to a learning environment.

In this chapter, the emphasis is on the different sensory modalities. Individuals perceive stimuli from the outside through the five senses, but each individual may have one or two of these senses more accurate than others. As such, he tends to acquire information more through that sense. This preference for a sensory modality has been investigated to explain the success or failure students have to assimilate certain learning content (e.g.: more orally or more in written form).

On the other hand, professors can use several didactic materials to deliver instruction to their students (particularly in eLearning). Text, images and diagrams, audio, video, simulations are all valid means to deliver pedagogical information. But which of these means suites best a particular learning style?

This chapter discusses the contribution of screencasts as one possible solution to that problem. A screencast is a digital recording of computer screen output, including mouse movements and clicks. Also known as a video screen capture, screencasts can include audio narration to explain the process that is being documented by the screencast. If well

planned and recorded, screencasts can include text, images, diagrams, audio, video and simulations, thus aiming to reach several learning modalities, including the preferred one of a particular student.

BACKGROUND

What Are Learning / Cognitive Styles?

One of the pioneers of the term ‘cognitive styles’ was Gordon Allport (1937), which defined them as the usual or typical way of an individual processing information. In other words how he perceives, thinks and remembers information, and how he uses it to solve problems. Since then, there have been many researchers who have dedicated themselves to study this concept, with the consequent identification of different cognitive and learning styles. For example, the work of Messick (1976) identified 19 different dimensions of cognitive styles (field dependence versus field independence, global versus analytic, inductive versus deductive, visualizer versus verbalizer, etc.), some of which are referred in the Additional Readings section.

Before moving on, it should be clarified that in this chapter, like in most of the area’s texts, the terms ‘cognitive styles’ and ‘learning styles’ are used to describe the same concept, although the first one is more used in the context of academic research, while the latter one is more related to their practical applications. Moreover, the term ‘cognitive styles’ is more connoted with a bipolar characteristic (e.g.: a student is either inductive

or deductive), while the term ‘learning styles’ does not require the existence of two poles (e.g.: one student may be visual and kinesthetic at the same time).

The VARK Model of Learning Styles

During the 1980s, and in informal conversations with college students, Neil Fleming realized that many of them attributed their learning difficulties, to the way learning content was presented. Some students said they had more difficulties with content presented orally; others, with written texts; some more, with ideas that were presented in graphical form; and others with subjects that were presented without any connection to practical applications. This finding led the author to focus on the sensory modalities as a dimension of learning styles with some prominence in relation to the other dimensions (Fleming & Mills, 1992).

In addition, the author found some basis for this assumption in his research in the neuro-linguistic programming area, which years before, had already identified three different sensory modalities – aural, visual, and kinesthetic – described below:

- *Aural* individuals learn best by listening, for example, to a lecture given by a teacher.
- *Visual* individuals learn best by viewing, for example, a video, an image, etc.
- *Kinesthetic* individuals learn best when, for example, attend a lecture but write what they hear or perform something practical.

Thus, more than studying the various dimensions of learning styles, which seemed to have little practical application for students (Fleming & Mills, 1992), Fleming was interested primarily in the sensory preferences of students, giving rise to what he designated the VARK model (which is an acronym for Visual, Aural, Read / write & Kinesthetic).

As noted by the acronym, Fleming added a second visual modality to the neuro-linguistic programming model referred above. It is the

read / write modality, because, according to the author, there are some students who prefer text content, i.e., written words basically, while other students prefer other symbolic forms to represent information such as maps, diagrams and charts. Although both preferences are visual, seldom they are present in the same person (Fleming & Baume, 2006).

In summary, the VARK model proposes the following sensory modalities to enhance learning (Fleming, 1995):

- **Visual:** Learning centered on viewing images, graphs and diagrams, as well as in color and formatting variations of documents (e.g.: highlighted boxes); good perception of symbolic information.
- **Aural:** Learning centered on hearing, i.e., using the ears to receive the commonest way to exchange information in society, which is speech.
- **Read / Write:** Learning through texts, that is, through the written word; it is called “read / write” because this type of students use reading and writing as the first choice to receive information.
- **Kinesthetic:** Multisensory and practical oriented learning, i.e., this type of students like to experience learning through all senses, and although they like to learn by doing, they can also learn concepts and more abstract materials, provided they are accompanied by concrete examples or real life scenarios (in a phrase, they like learning through action).

Each individual has one or more of these sensory modalities by which he prefers to learn, and there is a questionnaire with sixteen questions, which helps students to diagnose those preferences (VARK Learn Limited, 2016).

One of the advantages of this learning styles model is that, besides allowing to know the sensory preferences of an individual, it also provides study tips for more effective learning. This is because

the authors emphasize that the way information is presented to students, does not have to be the same in that they record it for later study. For example, if a teacher gives priority to oral presentations in his classes, a visual student should make diagrams and drawings in his notebook, which better reflect the verbal information he just heard (Fleming, 1995).

This VARK model priority – to promote the adaptation of students to the formats in which teachers present their contents – seemed more feasible to the authors, than to promote that teachers diversify their teaching methodologies (Fleming & Mills, 1992). This is because, knowing how to make this adjustment, students gain tools to get the best out of any course, and not only those in which the teacher diversifies his teaching materials to meet several sensory preferences. On the other hand, it is known that teachers tend to present their contents according to their own sensory preference (Fleming & Baume, 2006).

Nevertheless, the model also motivates teachers to reach as much sensory modalities as possible, and gives tips on how to design classes and teaching materials with that goal in mind. In fact, the VARK model dissemination among the teaching community made them more aware for the need to go beyond the most frequent presentation, which is the unimodal or, at most, bimodal (even with eLearning, that in many cases, only converts speech into text, i.e. the aural modality by the read / write modality) (Fleming & Baume, 2006).

In terms of the VARK questionnaire's statistical validity – i.e., can that instrument detect and classify correctly, the preferred learning modalities of students? – although there are potential problems related to item wording and the scale's scoring algorithm, there is evidence of VARK's validity for measuring learning preferences (Leite, Svinicki, & Shi, 2010). The potential problems are due to the fact that respondents can select more than an option, in each of the questionnaire's sixteen questions. Each question presents a scenario – e.g.: *"You have a problem with your heart."* – and four options for the respondent to choose his preferred sensory modality(ies) – e.g.: *"You would prefer*

that the doctor: (i) used a plastic model to show what was wrong; (ii) gave you something to read to explain what was wrong; (iii) described what was wrong; (iv) showed you a diagram of what was wrong."

Despite the limitations of the VARK model, that does not decrease its usefulness to illustrate that different students prefer to perceive teaching materials in different formats, which may help to explain the relations between screencasts and learning styles (the aim of this chapter).

Another common confusion is to consider VARK's sensory preferences as skills or strengths of individuals. However, to like something does not necessarily mean that a person is good at it, i.e. the VARK model helps to know how a student likes to communicate, but says nothing about the quality of that communication (Fleming & Baume, 2006).

Screencasts

A screencast is a digital recording of computer screen output, often accompanied by audio narration to explain the process being described (Peterson, 2007). As the PrintScreen key allows to capture the image of a computer screen, a screencast is a film of what can be seen in this screen, over a given period of time.

Hence there is the need for a specific software in order to record screencasts (a screencasting software), which besides recording what is happening on the screen, it also allows the edition of the screencast's sequences (e.g.: cutting a part where the speaker coughed), and the production of the final result in a universal file format (e.g.: Adobe Flash) (EDUCAUSE Learning Initiative, 2006).

However, unlike face-to-face classes that can be recorded with a traditional video camera, or even an audio recorder, classes that deal with computer-based content require a higher quality recording, in order to allow an effective viewing (and hearing) of the computer screen content. Normally, with regular video cameras one cannot achieve that quality.

Screencasts are typically indicated to show tasks that are performed with a computer (such as how to operate with a particular software), but not only...

Within a course, the demonstrative tasks are the first candidates to be recorded in screencasts (e.g.: “How to search a scientific database?”). However, also the lectures can be made available in screencasts, not just to be accessible to students who miss face-to-face classes, but also because these classes can be more effective this way than face-to-face (at least for some students). Why? Basically for these three reasons (Jesus & Moreira, 2009):

- Unlike a classroom lecture, students can view the screencasts when they want to, especially in the times of the day that enhance their ability to concentrate / retain the subject matter (e.g.: there are students who prefer to study in the evening, others in the morning, etc.).
- In addition, there are students who feel that the classroom environment contains a certain ‘noise’ – e.g.: the whispering from behind, the side colleague who asks a question – that hinder the full message reception transmitted by the teacher. When viewing the screencast of the class, the student can eliminate this ‘noise’.
- Furthermore, the student can stop the screencast when he wants to and continue viewing it later; or else, if he gets confused, he can rewind the screencast, and repeat the visualization of the most difficult parts to understand them better. The same goes even weeks or months later – the student can always go back to the screencast to refresh his memory in relation to any topic of interest.

Of course, these reasons apply to screencasts of all kinds of classes, but with particular relevance to lectures, because they can address contents of a higher level of abstraction.

Another major advantage of screencasts is that the recording task does not require a class taking place face-to-face, in order to be recorded “live”. The recording phase can (and should) be conducted during the planning of classes, prior to the beginning of the school year. Thus, screencasts of all the course’s subjects can be delivered to students in the first day of the semester. Among other things, this means that the most interested students can also view the screencast of the next class before it takes place. Those who do, will take an additional advantage of screencasts – use them to prepare face-to-face classes, taking advantage of the time with the professor, mostly to elucidate questions and doubts that did not get perfectly understood by simply viewing the screencast. This is the major teaching strategy advocated by flipped learning supporters (Faculty Focus, 2015).

SCREENCASTS AND LEARNING STYLES: A CASE STUDY

In order to discover if there is a relation between screencasts and sensory preferences, a study was designed with a group of nursing students. What kind of students, i.e., with what kind of sensory preferences, would value the most, learning through screencasts? Are screencasts more valued by multimodal students than by unimodal ones? These are some of the questions that this section tries to answer. It starts by identifying the research methodology, followed by the major results found and its discussion.

Methods

The author of this chapter is the professor of a statistics course whose participants are third year students from the Instituto Politécnico de Saúde do Norte (IPSN, a Portuguese private higher education school; URL: <http://www.cespu.pt/en/>). The course aims to prepare nursing students to conduct research projects in their field. With a 2-hour class per week (face-to-face), a page

in a Moodle platform, and screencasts of all the course's subjects to support the course during and between classes, the unit of Introduction to Research takes place in a fully equipped classroom with personal computers and broadband Internet connection.

A transversal study was conducted, at the beginning of 2015/2016 academic year, where 57 undergraduate nursing students (convenience sample) filled out the VARK questionnaire (version 7.1) (VARK Learn Limited, 2016), and another survey with sociodemographic questions, as well as questions related to the usefulness and satisfaction with screencasts, Moodle resources and face-to-face classes.

Besides those two questionnaires, data collection methods included the students' ratings in the course's assessment moments, and the Moodle's log files information, besides the records of class attendance. All this information was stored and utilized for analysis after removing all individual identification data in order to protect the research subjects' privacy. The participants were informed of that practice prior to the beginning of the study, and signed a consent form approving that method.

The collected data was analyzed with descriptive and inferential statistics methods (using SPSS version 23). Correlation between VARK scores and screencasts satisfaction, as well as mean differences tests (e.g.: Mann-Whitney U test) were utilized to answer the research questions, always with a significance level of 0.05.

Results and Discussion

The following topics summarize the sample characterization:

- 57 students with more females than males (3/4 versus 1/4);
- The vast majority (86%) were traditional students (coming directly from high school to higher education), with a span of 20 – 22 years of age;

- Almost all students (90%) have chosen the bachelor's degree in Nursing as their first choice in higher education (hence, they were motivated);
- For almost all students (93%) it was the first time they watched screencasts;
- For three quarters of students it was the first time they accessed a Moodle platform;
- The students ended the curricular unit with good grades (median of 14.1 ± 2.4 in a scale of zero to 20), and only 4 students failed to approve.

VARK Modalities and Scores

Figure 1 shows that the majority of these students were multimodal (61.4%), as opposed to unimodal (38.6%). This result is in line with the general population (VARK Learn Limited, 2015), as well as with other samples of medical students (Prithishkumar & Michael, 2014) (Samarakoon, Tharanga, Rodrigo, & Rajapakse, 2013) (D'Amore, James, & Mitchel, 2012). In the multimodal subgroup, quad modal (VARK) was the predominant style, with 29.8% of all students. In the unimodal subgroup, the aural modality (mild, strong and very strong) was the predominant one, with 21.1% of all students.

As for the frequency of V, A, R and K scores, calculated from the questionnaire, remember that each individual score varies from zero to 16 (the number of items in the questionnaire). But as there were students who chose more than one option in each question (i.e., who chose more than one sensory preference), it is best to convert the scores into the scale of zero to 100%. Thus, if a student only chose one sensory preference in each one of the 16 questions, each score was divided by 16 to obtain the percentage. But if a student chose more than one sensory preference in the survey questions, each score was divided by the total number of options that the student has selected (> 16). Figure 2 illustrates the average frequency of each V, A, R and K scores, in percentage, for all respondents. Thus, in the scale of zero to

Figure 1. Students' learning styles (general VARK questionnaire result)

100%, predominated the aural modality (average score of $31.67\% \pm 10.57\%$), then the read / write modality (average score of $26.86\% \pm 8.6\%$), followed by the kinesthetic modality (average score of $25.33\% \pm 10.08\%$), and finally, the visual modality (average score of $16.13\% \pm 8.52\%$). In other studies with medical students around the world, summarized in a recent literature review (Khanal, Shah, & Koirala, 2014), the predominant sensory modalities were the kinesthetic, followed by the aural. The kinesthetic being justified by the practical nature of health degrees (e.g.: clinical internships); and the aural being justified by the fact that students are used to lectures throughout their entire school path.

Students' Satisfaction with Screencasts

Figure 3 shows that more than three quarters of these students thought that oral explanations were the most useful component in the screencasts. In

other words, they valued the most the teacher's audio narration that explained the process being described by the screencasts. This result is consistent with the predominant aural modality found above.

Followed by close and selected by 71.9% of all students, the examples and real scenarios were the second most valued component of screencasts. This component is more addressed to kinesthetic students, whose score was also well represented in this sample, as seen above.

Diagrams and illustrations (more addressed to visual students), and written text (more addressed to read / write students) were the least valued components of screencasts, referred by less than half of these students. And if the visual modality had the smallest average score in this sample (16.13%), it is strange that the written text was so poorly evaluated by students, because in terms of average scores, the RW modality was the second most predominant in this group of students. Maybe the media rich context of screencasts, which

Figure 2. Students' average scores in the VARK questionnaire

Figure 3. Most useful component in the screencasts, for students

can include images, diagrams, audio, video and simulations, has relegated the text component to an inferior rank, in these students' opinion.

Relations Between Screencasts and Learning Styles

Based on several questions that were present in the second questionnaire (such as: "*How useful were screencasts / Moodle / classes for your learning experience?*", "*Describe how did you prepared yourself for the final exam*", and "*In the future, when you need to apply the skills and knowledge that you have learned in this unit, what kind of*

resources will you use?"), a total utility score was computed for each one of the three major didactic materials of this course: screencasts, Moodle and face-to-face classes.

Figure 4 illustrates that multimodal students found screencasts to be more useful than face-to-face classes and Moodle resources (screencasts' median = 11; classes' median = 9; Moodle's median = 6), and those differences were statistically significant ($p = 0.006$; effect size = 17.5%). On the contrary, unimodal students found face-to-face classes to be more useful than screencasts and Moodle resources (classes' median = 10.5; screencasts' median = 9.5; Moodle's median =

Figure 4. Usefulness of screencasts, Moodle and face-to-face classes, for the students learning experience

7.5), although those differences were not statistically significant ($p = 0.074$). This shows that screencasts are more appealing to multimodal students, and face-to-face classes are more appealing to unimodal students.

Comparing each component between multimodal and unimodal students, only in the screencasts component there is a higher usefulness perception of multimodal students, compared with unimodal ones (multimodal median = 11 versus unimodal median = 9.5). Both in Moodle resources and in face-to-face classes, unimodal students have perceived more value than multimodal ones (Moodle unimodal median = 7.5 versus Moodle multimodal median = 6; classes' unimodal median = 10.5 versus classes' multimodal median = 9). However, none of these between groups differences were found to be statistically significant.

Following there are other findings that try to answer to the question: "What kind of students, i.e., with what kind of sensory preferences, would value the most, learning through screencasts?":

- Students who found that the most useful component were screencasts, had an aural score lower than those who found that the

most useful component were face-to-face classes (classes' median aural score = 33.3 versus screencasts' median aural score = 26.1; $p = 0.011$; effect size = 11.7%);

- As the students' visual score increases, so does the enjoyment for learning through screencasts ($\rho = 0.34$, $p = 0.009$), and the amount of time invested on watching them ($\rho = 0.47$, $p < 0.001$);
- As the students' visual score increases, the enjoyment for learning through classes decreases ($\rho = -0.33$, $p = 0.012$).

This reveals that, in this sample, visual students were the ones who valued the most, learning through screencasts; and aural students were the ones who valued the most, learning through face-to-face classes. But caution interpreting the previous sentence because the majority of these students were multimodal (61.4%), as opposed to unimodal (38.6%). So, the majority of these students had multiple sensory preferences, and cannot be considered just 'visual students', nor just 'aural students'.

FUTURE RESEARCH DIRECTIONS

Taking into account that, in this experiment, students were only recipients of screencasts, it would be interesting to see how they would behave, if they were creators of screencasts. From this idea, one could design multiple experiences. For example, what would be the effects on their learning, if students were asked to design screencasts on certain thematic units, in order to share them with the rest of the class? Or, what if instead of writing a paper, students could present the results of their research project in screencast format? What kind of students (e.g., multimodal vs. unimodal) would be the best screencasts' creators?

Another suggestion is to test the feasibility of screencasts in eLearning assessments. As one knows, in eLearning settings is very difficult to warrant that the person doing the evaluation is the student himself. What if it was mandatory for students, to record their assessment test in a screencast (with voice narration), and send it to the teacher at the end of it? How would students react to this new form of surveillance? Would they have technical difficulties to record and submit screencasts? Would this new variant of evaluation – evaluate how you get to the end result, and not just the final outcome – would be beneficial to the students' learning process? These questions are pertinent to validate this proposed model of evaluation in eLearning.

CONCLUSION

Learning styles are not mutually exclusive categories but preferences that may be mild, moderate or strong. This explains the wide variation among learners with the same learning styles, when prior knowledge, experience, and skill level are factored into the learning style equation.

Can a teacher design instruction that addresses all these individual differences? Of course not and neither is that the point. But if teachers diversify their teaching methodologies, in order to achieve

a good balance, for instance with respect to the sensory channels that they appeal, the chances of different kinds of students feel comfortable with learning the teacher's message will increase, thus promoting a better learning experience for all.

Screencasts seem to be a good solution for this diversity, because they can include text, images, diagrams, audio, video and simulations, thus aiming to reach several learning modalities, including the preferred one of a particular student. In favor of this solution is the fact that, in a sample of undergraduate students examined by the author, screencasts were found to be more appealing to the multimodal ones (the majority of the sample and also of society in general (VARK Learn Limited, 2015)). Inversely, unimodal students (which were strongly composed by aural learners) found face-to-face classes more appealing to their learning, probably because they are lectures to a great extent. Prithishkumar & Michael (2014) also advocate the use of screencasts as a way to diversify the teaching strategies that reach several learning styles.

There is one last enduring message to be taken from the debate about learning styles. Addressing the learning needs of students is way more complicated than it seems. The ideal balance among learning style categories depends on the subject, level, and learning objectives of the course and the backgrounds and skills of students. That is the problem teachers should be working to solve but without expecting a single right answer.

KEY TERMS AND DEFINITIONS

eLearning: Contraction of electronic learning. Interactive training, available through the Internet or other means of electronic communication,

making the learning process independent of time and place.

Learning Style: Usual way of an individual processing information. How he/she perceives, thinks and remembers information, and how he/she uses it to solve problems.

Moodle: Open source learning management system used by all types of schools and training centers, to add web technology to their courses.

Multimodal Student: A student that has two, three or even the four VARK Model dimensions equally developed. He/she prefers to use several sensory channels to acquire information.

Screencast: Digital recording of computer screen output, including audio voiceover.

Sensory Modalities: Senses through which humans perceive stimuli from the outside world.

Unimodal Student: A student that has one of the four VARK Model dimensions more developed than the other three. He/she prefers to use a single sensory channel to acquire information.

VARK Model: Model of learning styles based in the sensory preferences of students. Its 4 dimensions (which form the model's acronym) are: Visual, Aural, Read / write and Kinesthetic.

Self-Awareness and Motivation Contrasting ESL and NEET Using the SAVE System

INTRODUCTION

Youth unemployment has been increasing over time in the last 10 years, although with very different rates, in all Countries. The last economic crisis has intensified the phenomenon of people being not in education, employment or training (NEET), extending it to areas where it was most content. According to OECD (2016), about 15% of youth aged 15 to 29 (corresponding to roughly 40 million young people) are NEET. However, crisis represents only a contingent factor: effective policies and intervention should address their structural drivers, mainly related to the quality of the educational, VET and job market systems and dynamics, as well as their dynamic alignment (Eurydice and Cedefop, 2014; Global Opportunity Report, 2016). It is well documented that reduced employment opportunities and increased likelihood of unemployment, poverty and social exclusion is strictly linked to early leaving from education and training (OECD 2012; European Commission, 2011).

The strong correlation between education and employment, links the NEET and early school leaving (ESL) phenomena in a vicious circle (Eurostat 2016) having negative impacts on social

inclusion and development, also in a medium-long term perspective. Young people with low level of education are three times more likely to become NEET compared to the others (Eurofound report 2012). The core issue of this relationship is not merely related to a lack of “professionalization”; it also calls for the progressive lack of expectations and motivations and in turn, in very low (or absent) active youth behaviours. The consequent vicious circle between ESL and NEET brings serious social and economical impacts, also in a long term perspective.

Although the both are featured by very diverse sub-groups and driving factors, three main common features and intervention directions emerge as critical: the improvement of the guidance, training and orienting systems in terms of learning and orienting personalization; the stronger focus on the active engagement and motivational aspects; the employment of a multi-dimensional and multi-actor approach, addressing contemporarily system, trainers, targets (European Commission, 2015; Eurydice and Cedefop report, 2014).

Referring to this scenario, this paper provides a review of the main effective approaches to contrast ESL and NEET phenomena; presents the methodological framework and the technology enhanced

DOI: 10.4018/978-1-5225-2255-3.ch135

guidance and learning system, integrating the main effective methodological approaches in an embedded Instructional Design System, guiding both the learners and trainers to the curriculum development and building of digital portfolio. The System, aimed at supporting trainers to contrast ESL and NEET phenomena, particularly in Vocational Education and Training (VET), is designed within a European project, named SAVE - Self Awareness, evaluation and motivation system Enhancing learning and integration and contrast ESL and NEET - 2014-1-IT01-KA202-002472 carried on by an European partnership (IT, ES, CZ, UK) under Program ERASMUS +. Then the article presents the result of the SAVE system piloting, engaging over 60 trainers and about 250 students in Europe, especially in Italy, UK and Spain; last discusses the further implications, challenges and effort required to prevent ESL and NEET.

BACKGROUND: MAIN DRIVERS AND POLICIES TO REDUCE THE PHENOMENON OF ESL AND NEETS

The heterogeneity of the NEET phenomenon is largely agreed, in terms of driving factors. Starting from the relation with ESL and, generally, with the educational level, other common causes emerging as critical refer to family and other social background factors and to school/work transition, Labour Market access, guidance system (Italia Lavoro, 2011; Eurofund, 2012; EU Commission, 2015 a). One of the main issues is the “lack of ownership” existing in the current setting, with many NEETs, particularly for 16/17 year olds, having little or no contact with institutions. This creates a serious risk of disconnection and by the time they enter the “formal” system, the damage may already be done.

A combination of personal, social, economic, educational and family-related factors, combined with certain features of education and training systems may aggravate the educational disadvantage, generating additional barriers for learners

who are struggling and delay their educational pathways. Creating an outcome related intervention with a focus on prevention and development of skills, rather than recovery, therefore appears essential. It appears even more essential when addressing the impacts of this “disconnection” on the motivational dimension, playing a central role, confirmed by the Eurofound report (2012) that distinguishes the NEETs population in subgroups in terms of engagement degree, from “disengaged” to “opportunity seekers”; and the last EU Report on dropout in Europe (2015 a), stressing the importance of the active engagement of youth and learning personalization as key factors. Researches show (Eurydice and Cedefop 2014) that systems characterized by grade retention, early insufficient support for learners, lack of quality vocational education and training (VET) [...] *The evidence suggests that individualising instruction and aid is likely to be more effective and resource efficient measure than making students repeat a year of study. A pedagogical practice that meets the needs of all students requires a flexible curriculum. [...] the evaluation of students' performance through the different combination of continuous formative assessment and external assessment is also crucial in this respects.* (Overcoming failure at school OECD 1998 p. 57).

According to the European DG Education and Culture (EU Commission, 2015), Policies to reduce ESL should be embedded in a whole school approach based on a stronger cooperation with a wide range of stakeholders (e.g. social services, outreach care workers, psychologists, guidance specialists, local authorities, business, unions, etc.); and in an overall inclusive learner-centred vision of education. That means to implement:

- A stimulating and conducive learning climate;
- Engaging curricula and effective teaching approaches;
- The learners' well-being;
- The learners' voice and participation in school life;

- Career education and guidance;
- Extra-curricular activities;
- Early detection mechanisms;
- A systemic support framework;
- Specific support for non-native speakers.

Furthermore, researches show that, in order to prevent ESL and disengagement, the curriculum should be linked to clear learning goals, and be connected to the next education (or professional) level. As much as possible, classroom activities related to the curriculum should develop student knowledge of real world problems (Dumont, Istance and Benavides, OECD 2010; OECD 2012). Students differ in ability, conceptions of learning, learning styles and strategies, interest, motivation, self-efficacy beliefs and emotion, as well as in their linguistic, cultural and social backgrounds. Students bring to the classroom different prior knowledge that substantially influences their learning process, and there is a constant and complex interaction between capacity and experience that shapes learning. That is why a set of guiding principles of learning environment are highlighted:

- **Learner-Centred:** Dependent on learner, not as an alternative to the critical role of teachers;
- **Personalised:** Sensitive to individual and group differences in background, prior knowledge, motivation and abilities, and offers tailored and detailed feedback.
- **Inclusive:** Able to valorise individual and group differences, including the weakest learners, in an educational agenda that excludes no-one.
- **Social:** Taking place in group settings, in a community that is itself the learning environment, inspired to collaborative strategy.

Summarising, NEETs population differentiations need to be addressed by policies, interventions and programs; at the same time, emerges a common and central role of motivational aspects.

This has represented (within a wider compared scenario carried on) the conceptual and operative

framework for the design and implementation of the SAVE methodological framework and technology enhanced system.

C

MAIN FOCUS OF THE ARTICLE: METHODOLOGICAL AND TECHNOLOGICAL FRAMEWORK TO CONTRAST AND PREVENT ESL AND NEET

The design of the SAVE methodological framework and digital system, takes move from the above mentioned background, addressing:

- Engagement and motivation of students by implementing effective self-awareness and evaluation tools and inclusive learning 2.0 solutions;
- Empowerment of the guidance role of trainers, by defining new pedagogical models, also technology enhanced, based on: self-evaluation; learning personalization and digital portfolio;
- Enhancement of the School and initial VET responsiveness, by leveraging on the competencies' recognition within the digital portfolio frame. The SAVE portfolio is a result of a self-reflection process driven in a motivational scale, helping to overcome the obstacles for children at risk of becoming NEET.

SAVE research confirmed the relevance of a twofold approach employing a multifactorial approach and valorising contemporarily: the active engagement of targets; the system capability in implementing learning and guidance personalised processes.

Furthermore, educators and employers agree that there is a growing gap between the Soft Skills that companies expect from their employees and those that many job candidates currently possess (OECD, 2015; CEDEFOP 2012; CEDEFOP 2008). With an increasingly competitive Job Market, it is imperative that job seekers are equipped

with a range of skills and competences that move beyond the technical knowledge and ability to perform specific tasks. These skills include emotional and social attributes allowing young people to demonstrate their motivation, self-confidence, ability to solve problems, initiative and communication/teamwork skills. In many cases young people are not aware of the soft skills they have, and even if they are aware, have difficulty in articulating them.

That is why a key goal of the SAVE project is to ensure that young people at risk of ESL and NEETs are provided with every opportunity to become, and to remain, actively engaged in learning in order to prevent exclusion from school and/or work. To this aim a range of interventions have been targeted at both:

- **Young People at Risk of Exclusion:** Improving their motivation and active engagement in learning and work by supporting their personal development, particularly in relation to their soft skills, self-esteem and by enhancing their employability;
- **Trainers:** Designing approaches, methods and resources supporting guidance and learning personalization and enhancing youth engagement and personal development.

Methodological Framework

Mistrust, the loss of self confidence, no perspective or vision about the future, no motivation, no interests, no expectations, no taking on responsibility, are the common feelings and attitudes of a NEET or ESL. That is why a learner-centered solution is necessary, involving all the dimension of the learner (Guspini 2009; Hoz 1982, 1997; Järvelä 2006, Meirieu 1992, 2004; Przesmycki 1991; Vettraino, Guglielma, Guspini; 2011), restarting from what the person is able to and from his/her potential. The SAVE methodological framework is based on strategies compliant with these requirements, aimed at the co-design of the

learning program and process (Przesmycki 1994), through a self-evaluation process (Guspini 2003; Varisco 2004; Davis 2001; De Bartolomeis 1974), of increasing complexity leading to the identification of learning challenges more than learning objectives, supported by digital portfolio's evidences (Cumming, Maxwell 1999; Wiggins 1993; Johnson, Rose 1997, Ajello, Belardi 2007).

The SAVE System integrates the main effective recalled methodological Learner-centred, Personalised approaches and Inclusive and Social learning environment, into an embedded Instructional Design System, guiding both the learners and trainers to the curriculum development. The system strategically combines from a methodological and technological point of view: motivational elements, evaluation strategies and digital portfolio resources to move along a self-realization scale where competences became visible.

Technological Framework

The SAVE system is supported by a customized Moodle platform. It embeds an instructional design model inspired to the ADDIE model (Analyse, Design, Develop, Implement, Evaluate), encouraging an active role of the students who go through the analysis phase, design develop and implementation, evaluation of the educational curriculum together with the guide of the trainer. So that another relevant implied technology is the students' mind (Hickman, 2000; Dewey 1910). Nevertheless, the digital support, the web services and the digital system guide the students and the trainers through the process of instructional design and curriculum development (Morrison, Gary, 2010), virtualizing this process, making it visible (Lévy, 1995) so that it can be retraced, appraised, improved, at any time. The SAVE portfolio mirrors this process, making visible all the accomplished tasks and progresses in real time. The SAVE System guides the climbing of the self-realization scale:

Step 1: I do not want

Step 2: I cannot

Step 3: I have not competences

Step 4: I will think about it

Step 5: I can

Step 6: I want

Step 7: Nothing can stop me

Step 8: I did it

Step 9: I did it better than I thought

A specific set of exercises corresponds at each step, presented by the following sections:

- **My Skills:** Contains resources and tools guiding the learner, from step 1 to 3, to acquire awareness about what s/he is able to. The learner collects all the information necessary to move to the next steps. (Analysis step of the Instructional design).
- **My Personal Plan:** Contains resources and tools guiding the learner, from step 4 to 6, to co-design with the coach a personal plan of development, oriented to the choice of an internship experience. (Design step of the Instructional design).
- **My Work Experience:** Provides the coach and the learner, from step 7 to 8, with tools and resources for collecting evidences of the work experience during the internship, to improve self-awareness of this experiences and give evidence to the related competences acquired and personal process; (Development/Implementation steps of the Instructional design).
- **My Portfolio:** Collects in real time the tangible results of the self-awareness rising process. It mirrors and live updates, step by step, the information recorded by the learner during each phase, leading to the step 9 (Evaluation step of the Instructional design).

The process is guided but it is not conditioned. The trainer provides suggestions and alerts; each page of the system shows information and instructions about steps progression, but the learner can move from a section to another. SAVE system structure integrates all the tools, frames and

supporting resources within a strategic, technology enhanced, learning personalization strategy. That is the characterizing element of SAVE: to be integrated in terms of actors, tools, strategies. Basically the trainers guide the learners in the effective use of the tools available in the System to improve their personal plan of development, to plan and realize an internship experience, to build and refine their portfolio. The trainers see exactly the same functions available for the learners, but having for each area of the system some guidelines on how to use each area, tool, resource. Moreover, trainers have control over the list of their learners and the correspondent process, in order to monitor and intervene when necessary with alerts, reminds, cockades.

In the section “My skills”, questionnaires and interviews, focused on what the students are able to, are the main support of the process. At the starting point questions offer closed options and descriptions: the students are asked to mirror with and choose the description that better fits with themselves. At the very beginning, indeed, students do not want, do not care, and do not willing (or are not able) to give deep personal descriptions. Time by time the interviews, encouraging and training self-reflection process, propose items of increasing openness and complexity. They move from closed questions with maximum three options, through a Self Awareness and Evaluation Diagnostic tool, to interviews based on biographical approach (Mezirow 2003; Demetrio, 2002).

For each questionnaire the coach can reinforce the self-awareness process by engaging the learner in simple tasks related to the information provided during the exercises. For example, if the learner states that s/he is able to cook a cake the trainer invites the learner to realize a cake and upload evidences of the artefact, reinforcing the accomplishment of the assigned task with virtual grades. The direct connection with a tangible result, with a real experience, more than with theories or contents, is a decisive variable in order to contrast the typical NEETs or ESLs attitudes and behaviours.

The Self Awareness and Evaluation Diagnostic (and its associated resources) is a core tool sup-

porting the learner to move along a self realization scale and enhancing trainers' supporting role. The questionnaire, focused on soft skills analysis, is designed to get young people to decide whether they agree or disagree to 48 statements about how they typically behave and like to work. Based on the range of potential answers to this questionnaire the Algorithm model for mixed variable programming was devised in order to produce individual reports. The questionnaire and its associated algorithms are loaded into the web-based SAVE Platform enabling learners to complete the questionnaire anywhere and at any time. It is loosely based on Marston's 4 Quadrant theory of Behaviour (4QB) (Marston, 1999). Designed to help young people become more 'self-aware', it uses the principles of personality profiling in order to analyse and feedback on the primary behavioural styles of the learners who have completed the assessment. The tool draws from a questionnaire and algorithms that have been particularly developed for use with young people who are at risk of becoming ESLs or NEETs.

The System seeks to identify an individual's primarily working style – how they prefer to work and interact – and to make young people more self-aware of these attributes. The outputs of the System suggest behavioural styles or preferences as well as strategies to make the most of strengths and cope with aspects of work, working relationships and learning that may not come easily to the learner. The outputs are designed to be positive and motivational. The benefits of this are twofold:

- As a result of taking the test and receiving professional feedback, the learners will have both greater self-awareness and increased confidence;
- For the trainers, the reports provide a useful insight into a learner's working strengths, style and potential thus providing an accurate and informed starting point for a Soft Skills development programme.

In order to use the Style Reports effectively, the trainer needs to recognise the primary behaviours

of each of the 4 styles identified by the diagnostic and understand how to work constructively with these when providing one to one feedback with a learner. To this extent, a Trainers Guide and associated resources includes: a description of the key characteristics of each of the 4 styles identified; guidance on how to explain the different styles to learners so that they become more Self Aware; how to use reports in order to draw up Individual Development Action Plans; a presentation for trainers to use with learners that explains the behavioural characteristics of the 4 styles, including their approach to learning and taking on new challenges; exercises and activities designed to support soft skill development.

The Self Awareness tool is integral part of the process leading to the portfolio development.

In the section "My personal plan", calendar functions, questionnaires and interviews are aimed at the co-design of a formative pact helping students to focus on their learning challenges and guiding to the choice of an internship experience.

In the section "My work experience", questionnaires and interviews guide and support learners to take notes and evidences on a virtual diary of their work experience, focusing on what they learnt and are able to.

The portfolio development is applied and integrated in this process, strictly connected with practical and real life, learning experience, or internship experience. All the proposed activities are finalized to support the choice of the apprenticeship experience or of a decision relevant for the learner. In SAVE the portfolio is then not a mere question of choosing format, tools or resources to fill in a folder. It is the arrival point of a progressive and recursive process of self awareness rising, aimed at moving from a condition of no motivation and mistrust toward a condition of gratification and motivation. At the very beginning the portfolio is merely a mirror of the learner profile. Step by step, the trainer supports the learner to improve the portfolio giving it an aspect more attained to the job perspective than to a mirror supporting the self-reflection. The trainer can suggest to re-phrase some sentences in a professional way.

The available qualification repertoires (i.e. European Qualification Framework) can be used to describe the acquired competences at the different level of expertise and mastery. SAVE portfolio starts as a self-reflection informal “mirror” and, step by step, ends in a more competence and job oriented working area that can be also valorised within external tool or networks (i.e. LinkedIn), or other social recruiting network and online job recruiting services.

EVIDENCES FROM THE SAVE SYSTEM APPLICATION

About 250 students at a risk of ESL, plus sixty teachers (engaged in Vocational Education and Training (VET), experienced the SAVE System, from June to October 2016. Validation activity with trainers, supporting an iterative process and the system on-going fine tuning has been carried out the year before.

Trainers and students, employing a multilevel and multidimensional assessment frame, have been asked to answer questions related to usability (and “utility”) main dimensions on all the areas, tools and resources of the system; trainers were also asked to observe the behaviour of the students using a common checklist. Indicators and descriptors of the checklist focused on behaviours of students showing: interest, concentration, completion of tasks. These behaviours indeed show antonyms attitudes compared with the usual approaches of NEETs or ESL. Furthermore, trainers were asked to add their interpretations and comments. A qualitative analysis of the collected remarks offered the following highlights.

The relationship between trainers and students experienced in the use of the SAVE System was mainly of one trainers to ten learners, from a minimum of one to three, and a maximum of one trainer to thirty learners. More than half of the trainers reported positive reactions of students showing interest, concentration, completion of tasks, together with an effective virtuous circle,

of increasing self confidence and awareness of areas of development by the students. trainers confirmed the effectiveness of the interview approach, focused on strengths, that gradually moves from multiple choice closed options, to opened biographic approach, as a powerful training of the self reflection attitude.

In order to enlarge, on a both qualitative and quantitative dimension, the feedbacks collected, the validation activities have been organised with different setting (from supporting the one-to one or small group guidance colloquium to the plenary class collective utilization and analysis of the system) and different target subgroups (in terms of age/class grade/curriculum).

A systematic observation would have required a longer elapse of time in a necessary longitudinal approach, for a more precise quantitative analysis. Nevertheless, the collected remarks, by a considerable sample of people, show a positive trend related to the system effectiveness. Almost the totality of answers related to the usability were positive, nevertheless students remarked that the graphic was not enough appealing and that they would have liked to have the system accessible and usable also by their mobile phone. Additionally, trainers and student highlighted the impact of the “reflective action” promoted by SAVE on the guidance and learning process and, more generally, on the personal development also in terms of “more aware” choices, improvement of the personal (and emotional) behaviour, enhancement of active behaviour. Finally, the first evidences from some focused validation action, also allowed to ground the valorisation of the improved awareness and transparency of competences (vertical but also behavioural) acquired, made visible by the digital portfolio.

FURTHER RESEARCH DIRECTIONS

The SAVE System, which encourages and motivates self awareness and self-evaluation is a valuable tool in helping young people to activate

a positive, aware and effective personal development (and employability) processes, supported by trainers within a more personalised guidance and learning systems. Coupled with the enhancement of active and personalised processes (at the centre of ESL&NEET prevention), the reflective and (self)evaluated processes promote the development (and awareness of the development) of soft skills, recognized as the core competences required to youths from companies and thus representing and essential elements of employability in addition to appropriate vocational.

However, these inputs represent only one piece, although central, of the puzzle. The question is, can schools, VET and colleges help provide young people with access to resources, on top of their educational attainment, supports more effective progression towards sustained employment? And if so, how can these organisations successfully provide resource to those young people whose personal circumstances make it hardest to access the experience, knowledge and contacts which might allow them to enter the labour market on a more even footing?

Work-based learning is a fundamental aspect of vocational training. It is directly linked to the mission of VET to help learners acquire knowledge, skills and competences which are essential in working life. The System, which supports the enhancement of the School and VET responsiveness, by leveraging on the competencies' recognition within the digital portfolio frame is a valuable tool in supporting trainers and employers within the management of the dual system application. To this extent, two evidences, among the others, can be quoted: some SAVE tools and resources will be valorised within the shared toolkit of the European Alliance for Apprenticeship; a dedicated toolkit for companies and job intermediates has been realised.

Creating opportunities for high-quality work-based learning as well as preventing and contrasting ESL and NEET are at the centre of the political and programmatic debates. The urgency of effective addressing both paths is referred to the high youth unemployment rate but also to the

vicious circle among ESL & NEET and its negative impacts: at the individual level, on personal development and social inclusion; at a system level, on the development of competitive, inclusive and innovative society.

CONCLUSION

There has been a broad range of interventions aimed in various different ways at tackling the issue of youth unemployment, ESL and NEETs. The most striking finding is how poor evaluations of these interventions are when it comes to attempting to judge successful programs. More needs to be done in this setting to ensure that we are able to identify which interventions are most effective in terms of outcomes and cost-effectiveness.

Consequently, SAVE open challenges and recommendations address both the policy and system level, the VET and job guidance system and the professional levels. Different considerations have been developed in each; the common frame is their integration. The most relevant effectiveness dimension is in fact the design and implementation of integrated policies and interventions, impacting contemporarily on youth motivation and evaluation and on system capacity in defining and managing personalized and engaging learning and guidance systems. Within this scenario and employing this approach, SAVE project has been designed and implemented. Actually the SAVE System is available by www.saveproject.it.

KEY TERMS AND DEFINITIONS

Learning Personalization: A learner centred approach aimed at involving all the dimensions of the learner (personal, emotional, vocational, etc.) encouraging the expression and development of personal attitudes and talents, in order to valorise the potential that each person can reach and express.

NEET: It is an acronym standing for “Not in Education, Employment or Training”, that in accordance with the International literature identifies people aged 15 to 29 demotivated to re-enter the Educational or Labour Market System.

Self Evaluation: A recursive process of self reflection, aimed at increasing awareness of strength points and areas of further development.

Customer Relationship Management

Analysis of Two Phases Queue With Vacations and Breakdowns Under T-Policy

Khalid Alnowibet

King Saud University, Saudi Arabia

Lotfi Tadj

Fairleigh Dickinson University, Canada

INTRODUCTION

Waiting in line is an experience that everyone practices, almost, on a daily basis. The waiting takes different forms and settings. Nowadays, the competition of customer satisfaction and low cost becomes very intense to the point that any customer that waits too long in line is potentially a lost customer to another compactor that provides better service or better waiting environment.

Waiting lines are basic in structure to the external (customer-facing) and the internal business processes. Queueing structures generally include staffing, scheduling and inventory levels. For this reason, businesses often utilize queueing theory as a competitive advantage. Although queueing is undesired for anyone, it is the cornerstone of efficiency and organization for many companies. The idea is simple: At any given moment, there can be more people or cases needing service, help or attention than an organization can handle. Queues help workers and managers track, prioritize and ensure the delivery of services and transactions.

The theory of waiting lines provides insight and identifies management options for improving customer service. A wide variety of queueing models have been developed and successfully exploited for very complex service situations. This chapter describes one such queueing model. For a comprehensive classification of various control policies applied in queueing systems, see the survey by Tadj and Choudhury (2005).

The service system considered in this chapter is characterized by an unreliable server. Random breakdowns occur on the server and the repair may not be immediate. It is assumed that at the end of a given service, the server may either take a vacation or start serving the next customer. When the queue is empty, the server again takes vacations and scans the queue periodically, every T units of time, to check if some customers have arrived while he was away. The third assumption is that the actual service of any arrival takes place in two consecutive phases. Both service phases are independent of each other.

BACKGROUND

The unreliability of the server is one of the main features of the queueing system studied in this chapter. Queueing systems prone to failure are commonly encountered in the real world. The server breakdown was first analyzed by White and Christie (1958). Since then, queueing systems with unreliable servers have been extensively studied by many researchers; see Tadj et al. (2012) for a comprehensive survey on the subject.

The next feature of the system of interest in this chapter is the Bernoulli vacation schedule. The classical vacation scheme with Bernoulli service discipline was introduced and developed by Keilson and Servi (1986). Various aspects of Bernoulli vacation models have been discussed

by a number of authors; see the survey of Ke et al. (2010).

The other important feature considered in our service system is the server T -policy. The M/G/1 queue with a T -policy was first studied by Heyman (1977). Many variants of the T -policy discipline model have been considered in the literature since then. There is no recent survey on the subject of T -policy discipline; however, some details of the latest contributions are listed here. Wang and Ke (2002) consider a single non-reliable server in the ordinary M/G/1 queueing system operating under the N -policy, the T -policy and the $\text{Min}(N, T)$ -policy. They show that the optimal N -policy and the optimal $\text{Min}(N, T)$ -policy are always superior to the optimal T -policy. Tadj (2003) studies an M/G/1 quorum queueing system under T -policy. The quorum or q -policy means that the server does not start service unless a specified number of customers are in the queue, and service is always rendered to groups of a fixed size. Ke (2005) studies an M/G/1 queueing system with an unreliable server, startup, and the following modified T -policy: After all the customers are served in the queue exhaustively, the server deactivates and takes at most J vacations of constant time length T repeatedly until at least one customer is found waiting in the queue upon returning from a vacation. If no customers arrive by the end of the J^{th} vacation, the server remains dormant in the system until at least one customer arrives. This model is generalized by Ke (2008) to the case of compound Poisson arrival process. More complex scenarios for the server are considered by Ke (2006). Kim and Moon (2006) study an M/G/1 queueing system where the server can take a vacation time T after the system becomes empty. At that time, the server is switched off with probability p and takes a vacation or remains on serving the arriving customers with probability $(1-p)$. Wang et al. (2009a) investigate the T -policy M/G/1 queue with server breakdowns and startup times. The server is turned on after a fixed length of time T repeatedly until at least one customer is present in the waiting line. The

same model is studied by Wang et al. (2009b) who use the maximum entropy approach to solve for the steady-state probabilities. Zhang et al. (2011) clarify the concept of regeneration cycle used in evaluating the average operating cost of the M/G/1 queue with T -policy. Two ways of defining the regeneration cycle are compared and advantages and disadvantages of each are pointed out.

Randomized control policies, with random control of the server at the beginning of the service when at least one customer appears, have also been combined recently with the T -policy. Yang et al. (2008) study the randomized T -policy in an unreliable M/G/1 queueing system with second optional service to the customers and server startup. Ke and Chu (2008) compare the randomized T -policy and the randomized N -policy for an M/G/1 queueing system with second optional service. Ke and Chu (2009) deal with a variation of the randomized T -policy of Ke and Chu (2008). Wang et al. (2010) compare the randomized T -policy and the randomized N -policy for an M/G/1 queueing system with second optional service and server startup. They show that the optimal randomized N -policy outperforms the optimal randomized T -policy. Kuo et al. (2015) obtain the optimal N - T threshold for a two-phase service M/G/1 system with vacation and random failure of service. In their system, they consider the case where the server starts service if queue length reaches threshold value N , or when the waiting time of the leading customers reaches time T . Also, Wua et al. (2014) study an M/G/1 queue with vacation under N -policy and a single phase of service. Where server is subject to breakdowns and the repair facility may fail during the repair period.

Recently there have been several contributions considering queueing systems of M/G/1 type in which the server may provide a second phase of service. The case where both phases of services are exponentially distributed is the so called Coxian distribution C_2 . Bertsimas and Papaconstantinou (1988) consider such distribution to design a multi-server queue with application in a transportation system. Madan (2000) studies an M/G/1 queue

where the server provides a first phase of regular service to all the arriving customers, whereas only some of them receive a second phase of optional service. The first regular service time follows a general distribution but the second optional service is assumed to be exponentially distributed. Some examples of queueing situations where such service mechanism can arise are also given. Medhi (2002) generalizes the model by considering the second optional service time is also governed by a general distribution. Recently, Choudhury (2003) investigates this queueing model in more depth and generalizes the results for a batch arrival queueing system with more than one optional service in (2003). Choudhury and Paul (2005) extend the two phase service model considering feedback. Krishnakumar et al (2002) consider an M/G/1 retrial queue with additional phase of service. The motivation for this type of model comes from some computer and communication networks where messages are processed in two stages by a single server. Further, Choudhury et al (2007) are able to develop the steady state distribution of the two phase service system with bulk arrivals and scheduled vacation.

MAIN FOCUS OF THE CHAPTER

The primary purpose of waiting lines theory is to obtain the performance measures of the service system. We thus obtain probability generating functions of the system state and the main performance measures such as the mean number of customers in the system, and the mean lengths of the idle period, busy period, and busy cycle. These measures are then used to design an optimal management policy of the system, by balancing various types of costs. We illustrate the results obtained by presenting a numerical example and perform some sensitivity analysis to show the effect of the system parameters on the optimal policy. The method of Zhang et al. (2011) is applied to obtain the system performance measures. These

will be used to find the vacation length that will optimize the system performance.

Model Description and Notation

The queueing system considered in this chapter is characterized by a single server and a Poisson arrival process with positive rate λ . It is assumed that the waiting room can accommodate an infinite number of customers. The server provides the service on a first-in, first-out discipline (FIFO). In addition, the actual service process takes place in two consecutive phases, a first phase of service (FPS) followed by a second phase of service (SPS). Let $i = 1$ correspond to FPS and $i = 2$ correspond to SPS. Let B_i denote the duration of phase i of service. Then, B_i is distributed according to the cumulative distribution function (CDF) denoted by $B_i(t)$ with Laplace-Stieltjes (LST) denoted by $B_i^*(\theta)$ and moments $b_i^{(j)}, j \geq 1$ and $i = 1, 2$.

During the actual service, the server may break down in any of the phases or in both. It is assumed that breakdowns occur independently in each phase according to a Poisson process with positive rate α_i ($i = 1, 2$). When a service interruption occurs, repair is delayed so that a delay period precedes the repair period. Let D_i denote the duration of the delay time during phase ($i = 1, 2$). Then, D_i is distributed according to the CDF given by $D_i(t)$ with LST given by $D_i^*(\theta)$ and moments $d_i^{(j)}, j \geq 1$ and $i = 1, 2$.

As soon as the server of phase i ($i = 1, 2$) is repaired, it immediately returns to provide his service until the queue becomes empty. Service time is the cumulative duration of actual service times, delays, and repair times. Thus, let R_i denote the duration of the repair time during phase i ($i = 1, 2$) of service. Then, R_i is distributed according to the CDF $R_i(t)$ with LST $R_i^*(\theta)$ and moments $r_i^{(j)}, j \geq 1$ and $i = 1, 2$.

Now, let H_i denote the duration of the modified service time of phase $(i = 1, 2)$. Then, H_i is distributed according to the CDF denoted by $H_i(t)$ with LST given by $H_i^*(\theta)$ and moments $h_i^{(j)}, j \geq 1$. Thus,

$$H_i^*(\theta) = B_i^* \left(\theta + \alpha_i \left(1 - D_i^*(\theta) R_i^*(\theta) \right) \right) \quad (1)$$

From Equation (1), the first two moments are defined as

$$\begin{aligned} h_i^{(1)} &= b_i^{(1)} \left[1 + \alpha_i \left(d_i^{(1)} + r_i^{(1)} \right) \right], \\ h_i^{(2)} &= b_i^{(2)} \left[1 + \alpha_i \left(d_i^{(1)} + r_i^{(1)} \right) \right]^2 + \alpha_i b_i^{(1)} \left(d_i^{(2)} + 2d_i^{(1)} r_i^{(1)} + r_i^{(2)} \right) \end{aligned} \quad (2)$$

Note that, in order to derive relation (1), the random variables B_i, D_i and $R_i (i=1, 2)$ are assumed to be independent of each other. This relation also allows determining the moments of the generalized service times in terms of the system parameters. Therefore, let H denote the duration of the generalized service time of a customer. Then $H = H_1 + H_2$ is distributed according to the CDF $H(t)$ with LST $H^*(\theta)$ and moments $h^{(j)}, j \geq 1$, so that

$$H^*(\theta) = H_1^*(\theta) H_2^*(\theta), \quad (3)$$

and

$$\begin{aligned} h^{(1)} &= h_1^{(1)} + h_2^{(1)}, \\ h^{(2)} &= h_1^{(2)} + 2h_1^{(1)} h_2^{(1)} + h_2^{(2)}. \end{aligned} \quad (4)$$

It is also assumed in this system that the server implements the Bernoulli vacation schedule, so that at the end of a service, the server may take a vacation of length T with some positive probability p , or may remain working with the complementary probability $q = 1 - p$. Let G denote the duration of the required service time

of a customer, which includes the generalized service time and a possible vacation. Then, G is distributed according to the CDF $G(t)$ with LST $G^*(\theta)$, and moments $g^{(j)}, j \geq 1$. Since

$$G = \begin{cases} H + T, & \text{with probability } p, \\ H, & \text{with probability } q, \end{cases}$$

we have

$$G^*(\theta) = (q + p e^{-\theta T}) H^*(\theta), \quad (5)$$

and

$$\begin{aligned} g^{(1)} &= h^{(1)} + pT, \\ g^{(2)} &= h^{(2)} + 2h^{(1)} pT + pT^2. \end{aligned} \quad (6)$$

The final main characteristics of the system is that the server takes a vacation if a customer departure leaves the system empty, in accordance with the T -policy. The server scans the queue T time units after the end of the last busy period (the beginning of the idle period). When the server finds at least one customer waiting in the queue, a busy period starts until the system becomes empty. Otherwise, if the server finds no customers waiting in the queue, another vacation starts, and a new scan is made after T units of time, and so on.

Additional Queue Size Distribution Due to the Idle Period

Suppose that after $\nu - 1$ vacations, the server finds no customer in the queue and after ν vacations, he finds Y_ν customers in the queue. Let $q(z) = e^{-\lambda T(1-z)}$ denote the probability generating function (PGF) of a Poisson random variable. Then, the probability mass functions of Y_ν and ν can be easily derived either by direct probability arguments or using fluctuation theory. Since

$P(Y = 0) = q(0)$ and $P(Y > 0) = 1 - q(0)$, we have

$$P(\nu = j) = [1 - q(0)]^{j-1} q(0), j \geq 1. \quad (7)$$

$$E[z^\nu] = \frac{z[1 - q(0)]}{1 - zq(0)}. \quad (8)$$

$$E[\nu] = \frac{1}{1 - e^{-\lambda T}}. \quad (9)$$

To obtain the distribution of Y_ν , let $k_j = e^{-\lambda T} \frac{(\lambda T)^j}{j!}$ denote the probability that j units arrive during a constant length of vacation time T . So,

$$P(Y_\nu = j) = \frac{k_j}{1 - q(0)}, j \geq 1. \quad (10)$$

$$E[z^{Y_\nu}] = \frac{q(z) - q(0)}{1 - q(0)}. \quad (11)$$

$$E[Y_\nu] = \lambda T E[\nu]. \quad (12)$$

The mean idle period is obtained, when the length of the idle period I , by utilizing Little's Law in expression (12), we get the expected length of the idle period as

$$I^{(1)} = \frac{\left. \frac{dE[z^{Y_\nu}]}{dz} \right|_{z=1}}{\lambda} = \frac{T}{1 - e^{-\lambda T}}. \quad (13)$$

Applying the discrete renewal theory the results (see Takagi (1990)), we can obtain the PGF of the number of arrivals during the residual life of an idle period as:

$$\psi(z) = \frac{1 - E[z^{Y_\nu}]}{\left. \frac{dE[z^{Y_\nu}]}{dz} \right|_{z=1} (1 - z)} = \frac{1 - e^{-\lambda T(1-z)}}{\lambda T(1 - z)}, \quad (14)$$

which is the PGF of the additional queue size distribution due the idle period for the T-policy model.

Queue Size Distribution at a Departure Epoch

Now, let $Q(t)$ denote the number of customers in the system at an arbitrary instant of time t and let Q_n be the number of customers in the system at the completion epoch T_n of the n^{th} service, that is, $Q_n = Q(T_n^+)$. Also, let V_{n+1} represent the number of customer arrivals during the $(n+1)^{\text{st}}$ required service. Then, Q_n satisfies the following recursion relation

$$Q_{n+1} = \begin{cases} Y_\nu + V_{n+1} - 1, & Q_n = 0, \\ Q_n + V_{n+1} - 1, & Q_n \geq 1. \end{cases} \quad (15)$$

Therefore, the process $\{Q_n; n = 0, 1, \dots\}$ is a Markov chain. Then, the i^{th} row of the transition probability matrix (TPM) A of the Markov chain $\{Q_n; n = 0, 1, \dots\}$ has PGF:

$$A_i(z) = \begin{cases} z^{-1} E[z^{Y_\nu}] E[z^{V_{n+1}}], & i = 0, \\ z^{i-1} G^*(\lambda - \lambda z), & i \geq 1, \end{cases} \quad (16)$$

where

$$E[z^{V_{n+1}}] = G^*(\lambda - \lambda z).$$

For the ergodicity of $\{Q_n\}$, Abolnikov and Dukhovny (1991) have shown that a Markov chain, whose TPM is a Δ -matrix, is ergodic if and only if

$$\left. \frac{dG^*(\lambda - \lambda z)}{dz} \right|_{z=0} < 1. \quad (17)$$

Since the TPM A is a Δ -matrix, it satisfies that:

$$\rho = \lambda g^{(1)} < 1. \quad (18)$$

Therefore, in the rest of the chapter, it is assumed that condition (18) is satisfied so that the Markov chain $\{Q_n; n = 0, 1, \dots\}$ is ergodic and a steady-state distribution for the number of customers in the system exists.

Now, denote by $P(z) = \sum_{i=0}^{\infty} p_i z^i$ the probability generating function of Q_n and by $p_i = \lim_{n \rightarrow \infty} P(Q_n = i)$ the steady-state probability of the number of customers present in the system.

Since $P(z) = \sum_{i=0}^{\infty} A_i(z) p_i$ then we have

$$P(z) = \frac{G^*(\lambda - \lambda z)(E[z^{Y_\nu}] - 1)p_0}{z - G^*(\lambda - \lambda z)}. \quad (19)$$

The summability-to-one condition $P(1) = 1$ yields

$$p_0 = \frac{1 - \rho}{E[Y_\nu]}, \quad (20)$$

where $E[Y_\nu]$ is given by (12). Combining equations (19) and (20), the steady-state probabilities for number of customers present in the system is defined for all n .

Queue Size Distribution at an Arbitrary Point in Time

The process $\{Q(t); t \geq 0\}$ is a semi-regenerative process relative to the sequence $\{T_n; n = 0, 1, \dots\}$ of service completion epochs. It is ergodic if and only if $\rho < 1$. Denote by $\pi(z) = \sum_{i=0}^{\infty} \pi_i z^i$ the probability generating function PGF in the steady-state of $Q(t)$ and by $\pi_i = \lim_{t \rightarrow \infty} P(Q(t) = i)$ the steady-state distribution. It can be shown using the main convergence theorem for semi-regenerative processes, see e.g., Çınlar (1975), that this PGF $\pi(z)$ is given by

$$\pi(z) = P(z). \quad (21)$$

Idle Period Distribution

Let I and $I^*(\theta)$ be the idle period random variable and its LST, respectively. Then, from the theory of fluctuating processes, it can be shown that

$$I^*(\theta) = \frac{e^{-\theta T}(1 - e^{-\lambda T})}{1 - e^{-(\theta + \lambda)T}}. \quad (22)$$

Delayed Busy Period Distribution

Let B and $B^*(\theta)$ be the busy period random variable and its LST, respectively. Then, from expression (11), we have

$$B^*(\theta) = \frac{e^{-\lambda T[1-\varpi^*(\theta)]} - e^{-\lambda T}}{1 - e^{-\lambda T}}, \quad (23)$$

where $\varpi^*(\theta)$ is the LST of the busy period of an ordinary unreliable M/G/1 queue under Bernoulli vacation schedule satisfying Takác's functional equation

$$\varpi^*(\theta) = (q + pe^{-\theta T}) \prod_{i=1}^2 H_i^*(\theta + \lambda - \lambda \varpi^*(\theta)). \quad (24)$$

System Performance Measures

One of our objectives of this analysis is to define the key important performance measures of the system in steady-state based on our findings. In this section we introduce the mathematical expressions for selected performance measures.

1. **Expected Number of Customers in the System:** This measure is found by:

$$L = \rho + \frac{\lambda T}{2} + \frac{\lambda^2 g_2}{2(1-\rho)}. \quad (25)$$

2. **Mean Idle Period:** The average time that a server remains idle is the time until the total workload accumulates to exceed the value T . Thus, the mean idle period, denoted by $I^{(1)}$ is equal to the mean first excess time. Then,

$$I^{(1)} = \frac{T}{1 - e^{-\lambda T}}. \quad (26)$$

3. **Mean Delayed Busy Period:** The busy period is the interval of time that keeps the server busy and this goes on until the first subsequent instant when the system becomes empty. Using equation (23), the mean delayed busy period is found to be

$$B^{(1)} = \frac{\lambda(h^{(1)} + pT)}{1 - \lambda h^{(1)}} \frac{T}{1 - e^{-\lambda T}}. \quad (27)$$

4. **Mean Busy Cycle:** The busy cycle is the difference between the starting times of two consecutive idle periods, $C^{(1)} = I^{(1)} + B^{(1)}$. So, the mean busy cycle is obtained by:

$$C^{(1)} = \frac{1 + \lambda p T}{1 - \lambda h^{(1)}} \frac{T}{1 - e^{-\lambda T}}. \quad (28)$$

5. **Probabilities of Idle and Busy Server:** Since the server takes vacations, the server may remain idle even with customers present in the system. Thus, the probability of idle server, denoted as π_0 , is given by:

$$P_I = \frac{I^{(1)}}{C^{(1)}} = 1 - \frac{\lambda(h^{(1)} + pT)}{1 - \lambda h^{(1)}}, \quad (29)$$

$$P_B = \frac{B^{(1)}}{C^{(1)}} = \frac{\lambda(h^{(1)} + pT)}{1 - \lambda h^{(1)}}.$$

6. **System Intensity:** The system intensity is defined by $\mathcal{I} = \sum P\beta$ where $P = (p_0, p_1, \dots)$ and $\beta = (\beta_0, \beta_1, \dots)$ with $\beta = E[T_{n+1} - T_n | Q_n = i]$. Since

$$\beta_i = \begin{cases} TE[\nu] + g_1, & i = 0, \\ g_1, & i \geq 1, \end{cases}$$

then we have

$$\mathcal{I} = \frac{\lambda T p_0}{1 - e^{-\lambda T}} + \lambda g_1. \quad (30)$$

Now using the expression found for p_0 in (20), we see that the system intensity is equal to the server load 1, as in the M/G/1 queueing system.

The quantity $P\beta$ is called the mean service cycle, and is equal to $1/\lambda$ both in the M/G/1 and in our model. This quantity needs to be finite and is essential when applying the main convergence theorem for semi-regenerative processes cited above.

Optimal Management Policy

Having obtained the required performance measures, we now are ready to develop a management policy for the system. We are interested in obtaining the optimal value of the length T of the vacation period. Denote by $TC(T)$ the total expected cost per unit of time where T is the decision variable. Then,

$$TC(T) = c_h L + c_o \frac{B^{(1)}}{C^{(1)}} + c_a \frac{I^{(1)}}{C^{(1)}} + c_s \frac{1}{C^{(1)}}, \quad (31)$$

where c_h is the holding cost per unit for each customer present in the system, c_o is the cost per unit time for keeping the server on and in operations, c_a is the startup cost per unit time for the preparatory work of the server before starting service, and c_s is the setup cost per busy cycle. We illustrate in the next section by some numerical results. Using the previous expressions, we have

$$TC(T) = c_h \left[\rho + \frac{\lambda T}{2} + \frac{\lambda^2 g_2}{2(1-\rho)} \right] + c_o \frac{\lambda(h^{(1)} + pT)}{1 - \lambda h^{(1)}} + c_a \left[1 - \frac{\lambda(h^{(1)} + pT)}{1 - \lambda h^{(1)}} \right] + c_s \frac{1 - \lambda h^{(1)}}{1 + \lambda pT} \frac{1 - e^{-\lambda T}}{T}. \quad (32)$$

The optimal value T^* is found by solving

$$\frac{dTC(T)}{dT} = 0. \quad (33)$$

The nonlinear expression (33) cannot be solved analytically. However, it can be solved numerically using some mathematical software such as MATLAB. Also, we don't compute the second derivative to show that the cost function is convex, although extensive numerical experiments suggest that it is.

Numerical Example

To illustrate the results obtained, assume the service times, the repair times, and the delay times all follow the exponential distribution. Therefore, the LST of the service time, the delay time and the repair time for each phase are given by $B_i^*(s)$, $D_i^*(s)$ and $R_i^*(s)$, ($i = 1, 2$), respectively which are defined as:

$$B_i^*(s) = \frac{1}{1 + sb_i^{(1)}}, D_i^*(s) = \frac{1}{1 + sd_i^{(1)}}, R_i^*(s) = \frac{1}{1 + sr_i^{(1)}}.$$

From expression (1) defined earlier, we get the LST for the modified service time given by:

$$H_i^*(\theta) = \left[1 + \left(\theta + \alpha_i - \alpha_i \left(\frac{1}{1 + \theta d_i^{(1)}} \right) \left(\frac{1}{1 + \theta r_i^{(1)}} \right) \right) b_i^{(1)} \right]^{-1}$$

It is assumed in this example that the arrival rate is $\lambda = 0.4$, the Bernoulli schedule probability is $p = 0.1$, the first phase breakdown rate $\alpha_1 = 0.01$ and the second phase breakdown rate $\alpha_2 = 0.02$. The moment's values of for each service phase are shown in Table 1. The monetary parameters were taken as follows:

$$c_h = 5, c_o = 20, c_a = 100, c_s = 200.$$

Figure 1 shows the variations of the expected total cost per unit of time. Clearly, the total cost function $TC(T)$ is a convex function of T . This means that $TC(T)$ has a global unique optimal

Table 1. Nonmonetary data

FPS Service Parameters	Value	FPS Service Parameters	Value
FPS Mean service time	$b_1^{(1)} = 0.05$	SPS Mean service time	$b_2^{(1)} = b_1^{(1)} / 2$
FPS Mean delay time	$d_1^{(1)} = b_1^{(1)} / 20$	SPS Mean delay time	$d_2^{(1)} = b_2^{(1)} / 20$
FPS Mean repair time	$r_1^{(1)} = b_1^{(1)} / 10$	SPS Mean repair time	$r_2^{(1)} = b_2^{(1)} / 10$

Figure 1. Variations of total expected cost per unit of time

value of T that minimizes the cost function. In this case, the optimal length of a vacation period is $T^* = 5.39$, which corresponds to an optimal cost per unit of time $TC(T^*) = 63.0476$.

Sensitivity Analysis

A sensitivity analysis is conducted to assess the effect of the main system parameters on the optimal policy. The first sensitivity analysis is conducted by varying the arrival rate λ from 0.125 arrival per unit of time to 0.375 and fixing all other values of the model. The second analysis is done by varying the values of the Bernoulli schedule probability p from 0.01 to 0.1. Table 2 shows that the optimal cost per unit of time decreases as p increases.

The analysis shows that the optimal value of T increases as the arrival rate increases. The optimal value of T converges to some value as the arrival rate takes high values. Details of the analysis are listed in Table 2 and Figure 2. However, the value of the optimal cost is a concave function with respect to the increase of the arrival rate (see Figure 2). In fact, the main purpose of applying control policies is to choose the best value of T that reduces the optimal cost. In the absence of the control policy it is expected that the total cost function strictly increases as the arrival rate increases.

With respect to the Bernoulli schedule probability, as the probability of taking a vacation increases the optimal T decreases. Similar to the effect of increasing the arrival rate, the optimal

policy value T seems to converge to some optimal value as the probability of vacation increases for higher values. (See Figure 3).

Figure 4 shows that the optimal total cost decreases linearly as the average service time for the first phase increases. The last analysis listed

in Table 5 represents the effect of changing breakdown rates for both service phases on optimal cost and optimal policy. Although, there is a relatively wide range of change in the breakdown rates the change in the total cost remains very limited. In addition, the optimal policy T^* remains

α_1 The Breakdown Rate of First Phase Service	0.1	63.049	63.049	63.050	63.050	63.050	63.051	63.051	63.051	63.051
	0.2	63.050	63.051	63.051	63.051	63.051	63.052	63.052	63.052	63.053
	0.3	63.051	63.052	63.052	63.052	63.053	63.053	63.053	63.054	63.054
	0.4	63.053	63.053	63.053	63.054	63.054	63.054	63.055	63.055	63.055
	0.5	63.054	63.054	63.055	63.055	63.055	63.055	63.056	63.056	63.056
	0.6	63.055	63.055	63.056	63.056	63.056	63.057	63.057	63.057	63.058
	0.7	63.056	63.057	63.057	63.057	63.058	63.058	63.058	63.059	63.059
	0.8	63.058	63.058	63.058	63.059	63.059	63.059	63.059	63.060	63.060
	0.9	63.059	63.059	63.059	63.060	63.060	63.060	63.061	63.061	63.061

the same for all cases ($T^* = 5.39$). This means that the effect of breakdown rate of either phase is very minimal on the performance of the entire system.

FUTURE RESEARCH DIRECTIONS

The theory of queues, as a part of business analytics, uses past business performance to drive business planning. From past data, system parameters such as arrival rate and service rate can be estimated. Queueing models are then applied to obtain performance measures, thus gaining insight into the current state of the business. As shown above, these performance measures can then be used to devise an optimal management policy for the firm. It is through the use of analytics that the firm gains a competitive edge. A large number of queueing models is available. However, the development of more models is imperative since they provide the analyst with a powerful tool for designing and evaluating the performance of service systems. For example, the model developed in this chapter can be generalized to the case of bulk arrival, batch service, or both.

CONCLUSION

We have considered in this chapter a queueing system under T-policy, that is, where the server checks the queue length periodically, every T units of time, during the idle period. Customers require two consecutive phases of service, and the server may break down while providing either phase of service. A Markov chain approach is used to obtain the steady state system size probabilities and different performance measures. The optimal value of the threshold level is obtained analytically. Similar analyses can be applied to more complex systems where either the arrival process or the service process is bulk. Combinations of the T-policy with either D-policy or N-policy are also possible.

KEY TERMS AND DEFINITIONS

Bernoulli Vacation Schedule: Service discipline specifying that, at the end of a service, the server may either take a vacation or serve the next customer.

Optimal Management Policy: Refers to the selection of a best element from some set of available alternatives.

Queue: A line of waiting persons, jobs, or objects.

Queueing System: Consists of three major components: (1) the source population and the way customers arrive to the system, (2) the serving systems, and (3) how customers exit the system.

Server Vacation: Term used when the server is not serving the customers and is performing some secondary job.

T-Policy: A service discipline specifying that, when the system is empty, the server takes vacations of fixed length T, as long as no customers arrive to the system.

Unreliable Server: A server that can breakdown while providing service, and become unavailable to customers.

Customer Lifetime Value

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

Customer lifetime value (CLV) is the present value of all future profits obtained from customers over the life of their relationship with a company (Benoit & van den Poel, 2009). Companies have been increasing their focus on establishing and maintaining the good customer relations during the customers' life in the company (Haenlein, Kaplan, & Beeser, 2007), and thus, researchers and practitioners have realized the importance of the lifetime value of customers. CLV is the value of a customer's entire lifetime with the company, forecasts in the literature usually focus on a short-time period (Donkers, Verhoef, & de Jong, 2007).

CLV has been studied under the name of customer value, customer equity, and customer profitability (Kahreh, Tive, Babania, & Hesani, 2014). CLV, as an important metric in customer relationship management (CRM), has attracted the widespread attention over the last decade (Chen & Fan, 2013). In relationship marketing, CLV is the discounted profit streams of a customer across the entire customer life cycle (Ma, Li, & Chen, 2008). Companies can manage customers with different age groups, gender, and self-construal characteristics with different strategies to maximize benefits at different levels of customer loyalty to improve CLV (Qi, Qu, Zhou, & Li, 2015).

This article aims to bridge the gap in the literature on the thorough literature consolidation of CLV. The extensive literatures of CLV provide a contribution to practitioners and researchers by indicating the important perspectives on CLV in order to maximize the impact of CLV in global marketing.

BACKGROUND

Berger et al. (2006) indicated that companies need to consider revenues and costs based on cash flow of profits in measuring CLV. CLV is the sum of the revenues gained from company's customers over the lifetime of transactions after the deduction of the total cost of attracting, selling, and servicing customers, taking into account the time value of money (Hwang, Jung, & Suh, 2004). Companies can be more profitable if they identify the most profitable customers and invest disproportionate marketing resources in them (Malthouse & Blattberg, 2005). A profitable customer is one who can create profits, increase revenues, and assist in reducing losses (Kotler & Armstrong, 1996), and the difference between the revenues and costs generated by a customer is CLV (Dwyer, 1989).

CLV is presented to evaluate customers in terms of recency, frequency, and monetary (RFM) variables (Cao, Yu, & Zhang, 2015), toward to describe the value of a client through time in terms of profitability (Moro, Cortez, & Rita, 2015). Measuring RFM is an important method to evaluate CLV (Liu & Shih, 2005). Bult and Wansbeek (1995) explained the RFM terms (i.e., recency, frequency, and monetary perspectives). R (Recency) is the period since the last purchase, and a lower value corresponds to a higher probability of the customers making a repeat purchase. F (Frequency) is the number of purchases made within a certain period. Higher frequency indicates higher loyalty. M (Monetary) is the amount of money spent during a certain period. A higher value indicates that the company should focus more on that customer (Bult & Wansbeek, 1995).

IMPORTANT PERSPECTIVES ON CUSTOMER LIFETIME VALUE

This section emphasizes the prospect of CLV and the importance of CLV in global marketing.

Prospect of Customer Lifetime Value

Customer lifetime value (CLV) is viewed as the present value of the future cash flows associated with a customer (Pfeifer, Haskins, & Conroy, 2005). The main goal of CLV is to specify the importance level of each customer for a company (Hiziroglu & Sengul, 2012). CLV considers a customer's value to the company based on predicted future costs and transactions (Kumar, 2010). Gladly et al. (2009) defined CLV as the discounted value of future marginal earnings, based on the customer's activity. Knowing the CLV of individual customers enables the decision maker to improve the customer segmentation and marketing resource allocation efforts (Kim & Lee, 2007) and this perspective will lead to the higher retention rates and profits for the company (Hawkes, 2000).

CLV models can estimate the value of a customer over the entire customer's lifetime (Kahreh et al., 2014). The application of CLV in marketing, used for segmenting customers or formulating strategies, has been found in literature (Cheng, Chiu, Cheng, & Wu, 2012). Kim et al. (2006) proposed a CLV computation model considering the past profit contribution, potential benefit, and defection probability of a customer. Kim et al. (2006) covered a framework for analyzing customer value, and segmenting customers based on their values, and applied their approach to formulating marketing strategies for a wireless communication service company. Shih and Liu (2008) proposed applying a collaborative filtering technique through CLV and customer demand to develop a product recommendation system.

Regarding CLV, a monetary value of a future relationship with a customer is a fundamental concept for the long-term management of the

customer base and the planning of marketing activities (Karvanen, Rantanen, & Luoma, 2014). Kahreh et al. (2014) indicated that data inputs commonly used when making CLV calculations include seven major factors (i.e., acquisition cost, churn rate, discount rate, retention cost, time period, periodic revenue, and profit margin). Acquisition cost is the amount of money a marketing department has to spend, on average, to acquire a single new customer. Acquisition cost is positively associated with customer retention, future profits, and current market values (Livne, Simpson, & Talmor, 2011). Customer retention is a major driver of CLV and is a key performance metric in marketing management (Becker, Spann, & Schulze, 2015).

Churn rate is the percentage of customers who end their relationship with a company in a given time period (Kahreh et al., 2014). Customer churn (or customer attrition) is key for measuring success in the logistics industry (Chen, Hu, & Hsieh, 2015). CLV model considers the past contribution, potential value, and churn probability at the same time (Kim, Kim, & Sohn, 2009). Discount rate is the cost of capital utilized to discount future revenue from a customer. Retention cost is the amount of money a company has to spend in a given time period to retain an existing customer. Time period is the unit of time into which a customer relationship is divided for analysis. Periodic revenue is the amount of revenue collected from a customer in the time period. Profit margin is the profit as a percentage of revenue (Kahreh et al., 2014).

Customer loyalty is a driver of CLV (Qi, Zhou, Chen, & Qu, 2012). The aim of customer loyalty programs in modern organizations is to identify and encourage those customers exhibiting a high CLV (Steinhoff & Palmatier, 2016). Regarding CLV, the differential unit cost of marginal effects, ceiling rate, efficiency, and allocation of spending on acquisition and retention to achieve market share growth can maximize customer equity (Tsao, 2013). Value creation through customer-to-customer exchange occurs when the perceived

benefits of a company's offering are increased as a result of customers' interaction with one another (Gruen, Osmonbekov, & Czaplewski, 2007).

Importance of Customer Lifetime Value in Global Marketing

The concept of CLV receives much attention from marketing practitioners and academicians (Blattberg, Malthouse, & Neslin, 2009). CRM has been widely adopted in modern business (Fang, Shyng, Lee, & Tzeng, 2012). CLV has been an important metric for CRM to evaluate the marketing decisions over the last decade (Borle, Singh, & Jain, 2008). As CRM has become popular, CLV has emphasized a longer relationship with the customers (Kim et al., 2009). Chan et al. (2010) utilized the CLV to predict the company's long-term return on investment. CLV models are employed in the field of marketing to evaluate the lifetime value of customers in conventional businesses (Etzion, Fisher, & Wasserkrug, 2005).

Applying CLV to guide marketing decisions significantly encourages companies to recognize the major differences among customers and begin to create business value (Pfeifer & Ovchinnikov, 2011). The combination of the CLVs of the company's current and future customers (net of acquisition costs) is a measure of the value of the company (Rust, Zeithaml, & Lemon, 2000). In the context of customer development, CLV can be used as the object to select the promotions for the cross-selling and up-selling (Khan, 2009). Mulhern (1999) utilized the concept of present value and future value to measure CLV from the financial perspective. Nadeem (2006) investigated the models of marketing strategy for the long-term and short-term CLVs in an e-business context.

CLV plays an essential role in designing the marketing programs and allocating the marketing resources (Benoit & van den Poel, 2009). Liu et al. (2007) applied different variables to CLV in the service context and defined several relationships to customer value. An important managerial task is to take an array of past retention numbers

for a given group of customers and project them into the future to make more accurate predictions about customer tenure and CLV (Fader & Hardie, 2007). In the context of customer retention, the individual-level CLV gives a sense of how much is being lost due to churn (Rosset, Neumann, Eick, & Vatnik, 2003), and the decrease of CLV is utilized as a criterion to define churners in noncontractual settings (Glady et al., 2009). Examples of non-contractual context are retail purchases where the company does not know whether a customer has defected or not (Singh, Borle, & Jain, 2009).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of CLV will provide the potential opportunities for future research. CRM is the managerial philosophy according to which the company's goal can be achieved through the identification and satisfaction of the customer's requirement (Kasemsap, 2015a). To be the successful global retailers, the ability to apply and adjust the retail marketing mix elements and retail brand strategy concerning specific target-market conditions and a wider global marketing strategy, is functionally important in retail settings (Kasemsap, 2015b).

Marketing strategies include all basic and long-term activities in the field of marketing, thus dealing with the analysis of the strategic situation of an organization and the formulation, evaluation and selection of market-oriented strategies and effectively contribute to the goals of the organization and its marketing objectives (Kasemsap, 2015c). The capability of social media in building brand in the global marketplace is practically important in modern advertising (Kasemsap, 2015d). Developing a good relationship with the target market is essential for brand management in global marketing (Kasemsap, 2016). An examination of linkages among CLV, CRM, brand management, marketing strategies, and social media platforms in global marketing would seem to be viable for future research efforts.

Consumer attitude toward products can be changed by highlighting the new functions of the products, by changing the beliefs the consumer has regarding the products, and by getting the consumer more involved in the products (Kasemsap, 2017a). Web mining techniques can be applied with the effective analysis of the clearly understood business needs and requirements (Kasemsap, 2017b). Business intelligence is the computer-based techniques used in analyzing business data, such as sales revenue by products or associated costs and incomes (Kasemsap, 2017c). In the customer-related supply chain processes, information sharing can help in formulating customer experience strategies, increase customer service effectiveness, and improve supply chain operations (Kasemsap, 2017d). Considering the relationships among CLV, consumer attitude, web mining, business intelligence, and information sharing in global marketing would be beneficial for future research directions.

CONCLUSION

This article highlighted the prospect of CLV and the importance of CLV in global marketing. CLV is the total of the financial profit, calculated from the existing period to the future. CLV develops the optimal strategies for customer engagement, promotes the understanding of potential value of a customer, and enables the workforce to effectively improve customer relationships. Companies utilizing CLV can practically plan for availability of the service or product by predicting the future demand by customers. CLV can be a good indicator for operational efficiency and customer satisfaction. CLV can be managed to implement the initiatives that extend the life span of a customer through brand loyalty, increase the frequency of purchases, and develop the directed marketing campaigns to find more customers with similar behaviors.

CLV is an important metric for determining how much money a company wants to spend on acquiring new customers and how much repeat

business a company can expect from certain consumers. CLV can be a crucial perspective for costs to be associated with the promotions and communications to attract the new customers and retain the existing customers. CLV can help individuals estimate a customer's monetary worth to a business after factoring in the value of the relationship with a customer over time. CLV can determine the amount that will be required to retain customer segment. Promoting CLV has the potential to enhance marketing performance and reach strategic goals in global marketing.

KEY TERMS AND DEFINITIONS

Customer: Individual that buys products or services.

Customer Equity: The value of potential future revenue generated by a company's customers in a lifetime.

Customer Lifetime Value: The total gain expressed on a net present value basis that a business expects from having an enduring commercial relationship with a customer over time.

Customer Loyalty: The likelihood of previous customers to continue to buy from a specific organization.

Customer Retention: The assessment of the product or service quality provided by a business that measures how loyal its customers are.

Customer Satisfaction: The degree of satisfaction provided by the products or services of a company.

Marketing: The social and managerial processes by which individuals or companies obtain what they need or want through creating, offering, and exchanging products with each other.

Revenue: The income that a government or company regularly receives.

Facilitating Customer Relationship Management in Modern Business

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

In a highly competitive market, companies need to maintain positive relationship with their customers (Hassan, Nawaz, Lashari, & Zafar, 2015). Customer relationship management (CRM) encompasses the broad perspectives of activities starting with the segmentation of customers in the database and continuing with acquiring new customers and retaining existing customers (Matis & Ilies, 2014). CRM systems are a group of information systems that enable organizations to contact customers and collect, store, and analyze customer data to provide a comprehensive view of their customers (Khodakarami & Chan, 2014). Customer data and information technology (IT) organize the groundwork upon which any successful CRM strategy is established (Tsai, 2011).

CRM becomes one of the most important business strategies in the digital age, thus involving organizational capability of managing business interactions with customers in an effective manner (Kasemsap, 2015a). CRM refers to a firm's activities for establishing and maintaining relationships with its customers (Kalaighnam & Varadarajan, 2012). The merger of CRM systems with social media technology has given way to a new concept of CRM that incorporates a more collaborative and network-focused approach to managing customer relationships (Trainor, Andzulis, Rapp, & Agnihotri, 2014).

CRM is a critical issue in services management (Cheng & Yang, 2013). CRM systems are essential for companies seeking growth and profits in the global marketplace (Heidemann, Klier, Landherr, & Zimmermann, 2013). Keramati et al. (2013)

indicated that the nature of CRM is multidimensional, and it is one of the most complicated innovations in modern organizations. Customer value, customer satisfaction, and brand loyalty have mediated positive effect on CRM performance (Kasemsap, 2014a). This article aims to bridge the gap in the literature on the thorough literature consolidation of CRM. The extensive literature of CRM provides a contribution to practitioners and researchers by describing the multifaceted applications of CRM in order to maximize the business impact of CRM in modern business.

BACKGROUND

Effective CRM has emerged as a strategic imperative for companies in every business (Benmoussa, 2005). CRM has been recognized as a set of methodologies and organizational processes to attract and retain customers through their increased customer satisfaction and customer loyalty (Cousment & van den Poel, 2008). CRM is used to define the process of creation and maintain relationship with customers (Hassan et al., 2015). CRM is defined as the adoption of IT to develop new customers and retain old customers so as to keep the long-term customer relationship, which aims to improve customer relationship and can help increase customer loyalty, customer retention, and customer profitability (Hennig-Thurau, Gwinner, & Gremler, 2002).

The rapid growth of CRM systems raises the opportunity within many firms to effectively utilize the customer data over time to secure competitive advantage in modern business (Eichorn, 2004).

CRM data is among the most important and comprehensive information available to executives in many organizations (Stein, Smith, & Lancioni, 2013). With the increasing importance of CRM in every industry domain, CRM classification practitioners demand a standardized framework with the streamlined data mining processes capable of delivering the satisfactory result for CRM data with all data mining challenges (Tu & Yang, 2013). CRM leverages information, technology, and people to create and deliver value to the targeted customer at a profit (Salim & Keramati, 2014).

CRM relational information process includes information reciprocity, information capture, information integration, information access, and information use, and expected the process to enable the facilitation of CRM performance (Jayachandran, Sharma, Kaufman, & Raman, 2005). CRM relational information processing is a process in which firms effectively engage in the systematic registration, integration, and analysis of customer information (Hillebrand, Nijholt, & Nijssen, 2011). The key objective of the CRM relational information process is a focus on initiating, maintaining, and retaining the long-term customer relationships (Becker, Greve, & Albers, 2009).

CHARACTERISTICS OF CUSTOMER RELATIONSHIP MANAGEMENT

This article describes the overview of CRM; CRM and technological utilization; and the facilitation of CRM in modern business.

Overview of Customer Relationship Management

Customer relationship management (CRM) has been widely recognized as an important business approach to build the long-term relationships with specific customers (Coltman, Devinney, & Midgley, 2011). CRM is recognized as a manage-

rial tool for guiding sales teams and supporting engineers and other specialists in developing sales prospects, creating appropriate business proposals, dealing with customer objections, and providing post-sales customer support (Agrawal, 2003). Chen and Popovich (2003) defined CRM as a cross-functional, customer-driven, and technology-integrated business process management strategy that maximizes relationships. Kumar and Reinartz (2006) considered CRM as the strategic approach of identifying the firm's customers that can be profitably served.

CRM applications are considered as the closed-loop systems focusing on a set of priorities and time-critical functions at the customer level (Ku, 2010). CRM includes four major dimensions (i.e., customer identification, customer attraction, customer retention, and customer lifetime value) toward developing the sustainable relationships (Ngai, Xiu, & Chau, 2009). Current models of customer lifetime value consider the discounted value of profits that a customer generates over an expected lifetime of relationship with the firm (Singh, Murthi, & Steffes, 2013). Providing free trials for the particular products is an essential way to give feedbacks to the customers toward promoting CRM (Wei, Lee, Chen, & Wu, 2013). Mohammad et al. (2013) stated that promoting CRM improves organizational performance in the tourism-related hotel industry.

CRM not only enhances the flow of information within an organization, makes it easier to store customer data, and increases information accessibility (Hillebrand et al., 2011), but also leads to the greater insights into customer needs, customer behavior, and customer expectations by developing and maintaining the interactive relationships (Spiller, Vlastic, & Yetton, 2007). The development of long-term relationship with customers and turning them into the loyal customers are the important aspects of successful marketing because customers are the crucial assets in modern business (Wang, 2013).

Customer Relationship Management and Technological Utilization

A large proportion of firms that adopt CRM technology find it challenging to integrate CRM technology into their core marketing processes and utilize CRM to improve their performance (Saini, Grewal, & Johnson, 2010). In the context of CRM, there are various metrics used to define firm performance, including financial performance (Noble, Sinha, & Kumar, 2002), the elements of the balanced scorecard (Chang, 2007), and those that are either process-related perspective (Kim & Kim, 2009) or sales-related perspective (Bodenberg, 2001), as well as those that are related to customer satisfaction and economic performance (Keramati, Mehrabi, & Mojir, 2010). CRM-compatible organizational alignment and CRM technology positively moderate the relationships between CRM processes and economic performance (Reinartz, Karfft, & Hoyer, 2004).

CRM recognizes the new capabilities enabled by the technological and social shifts concerning social media applications (Trainor, 2012). The CRM-performance link is fully mediated by differentiation and cost leadership (Reimann, Schilke, & Thomas, 2010). CRM can contribute to the advancement of the web mining research (Tuzhilin, 2012). IT is recognized as an important component of CRM (Chang, Park, & Chaib, 2010). The practices of IT, knowledge management, and project management efficiently support each other in order to achieve planned goals in modern business (Kasemsap, 2015b). CRM technology is viewed as the sales or marketing-centric tool that increases the employee's effectiveness (Crittenden, Peterson, & Albaum, 2010).

Social media (e.g., Facebook and Twitter) and Web 2.0 technologies can help promote CRM in modern business. Social media allows access to data and video information to a broad range of potential consumers (Kasemsap, 2015c). Social media technologies need to be integrated with CRM processes to establish the firm-level capabil-

ity that influences the organizational performance (Trainor et al., 2014). Social media technologies are integrated throughout the organization to facilitate the capability development and to moderate the capability-performance relationship (Nevo & Wade, 2010). Social media enables the creation of knowledge value chain to customize information and delivery for a technological business growth (Kasemsap, 2014b). Social media encourages individuals to be visible to others and establish connections with other people in modern organizations (Kasemsap, 2014c).

Facilitation of Customer Relationship Management in Modern Business

Interaction orientation and CRM readiness are recognized as the moderators on the relationship between CRM relational information processes and customer-based performance (Chang, Wong, & Fang, 2015). Interaction orientation supports the creation of a trustworthy relationship with customers and leads to an increase in customer loyalty (Homburg & Muller, 2011). Interaction orientation reflects a firm's ability to interact with its customers and to take advantage of information obtained from them through the successive interactions in order to achieve the profitable customer relationships (Ramani & Kumar, 2008). Interaction orientation is proposed to assist in the accomplishment of CRM relational information processes and promotes the customer-based performance (Chang et al., 2015).

Bohling et al. (2006) stated that successful implementation of CRM by firms depends on their strategic fit on CRM, marketing strategy, and cooperation in modern business. CRM implementation can be favorable if there is the effective cross-functional incorporation of people, operation, and marketing expertise that is promoted by the process of technology, application, and information (Richard, Thirkell, & Huff, 2007). It is worth emphasizing the role that employees can play in the achievement of organizational goals to

adopt CRM initiatives as part of its operational activities, such as call centers (Abdullateef, Muktar, Yusoff, & Ahmad, 2014). The successful CRM is depended on internal IT service capability (Yang, 2012). CRM failures have occurred through a lack of strategic focus (Frow & Payne, 2009).

CRM systems include three categories: operational systems (used for automation and increased efficiency of CRM processes), analytical systems (utilized for the analysis of customer data and knowledge), and collaborative systems (utilized to integrate the communication channels and the customer interaction touch points) (Geib, Kolbe, & Brenner, 2006). CRM systems are the information systems that enable organizations to contact with customers, provide services for them, store customer information, and analyze that information to provide a comprehensive view of the customers (Karakostas, Kardaras, & Papathanassiou, 2005). CRM systems help organizations acquire and generate customer knowledge (Khodakarami & Chan, 2014). Customer knowledge is the critical asset toward gaining the valuable activity for organizations (Winer, 2001). Knowledge for customers is required to support the customer's relations and satisfy the customer's knowledge needs (Smith & McKeen, 2005).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of CRM will provide the potential opportunities for future research. Regarding the increasing advances in technology, IT and knowledge management effectively improve the strategic tools for providing the direct link between customers and tourism organizations, thus encouraging the communication channels in global tourism (Kasemsap, 2016). Understanding the importance of good customer service is essential for a profitable business in creating new customers, keeping loyal customers, and developing referrals for future customers. Customer experience is the

practice of designing and reacting to customer interactions for the purpose of meeting customer expectations, thus increasing customer satisfaction and customer loyalty.

Customer orientation is the important approach to sales and customer-relations in which executives and marketing professionals focus on helping customers to meet their long-term needs and wants. Customer satisfaction is the significant outcome of good marketing practice. Customer satisfaction is valuable from both a customer goodwill perspective and an organization's financial perspective. The study of consumer behavior helps marketers recognize and forecast the purchase behavior of the consumers while they are purchasing a product, toward increasing customer satisfaction. The relationships among CRM, IT, knowledge management, customer service, customer experience, customer orientation, customer satisfaction, and consumer behavior will be the important topics for future research directions.

CONCLUSION

The overview of CRM; CRM and technological utilization; and the facilitation of CRM in modern business are highlighted in this article. Efficiently dealing with all customers and providing them what they actually need increases the customer satisfaction. This increases the chance of getting more business which ultimately enhances turnover and profit. CRM is the important strategy to learn more about customer needs and customer behaviors in order to develop the stronger relationships with them. CRM is the most efficient approach in maintaining and creating the relationships with customers in modern business. CRM helps business gain the insight into the behavior of their customers and modify their business operations to ensure that customers are served in the best possible way.

Modern organizations should have an effective CRM system to cope up with all the business

needs. CRM helps business recognize the value of its customers and to capitalize on the improved customer relations. CRM system is utilized to deal with the existing customers and is also useful in acquiring new customers. CRM involves a historical view and analysis of all the acquired or to be acquired customers. CRM can predict customer requirements and can increase business growth. Installing a CRM system can definitely improve the business solutions and can help in challenging the new ways of marketing and business in an efficient manner. Facilitating CRM has the potential to enhance organizational performance and gain sustainable competitive advantage in modern business.

KEY TERMS AND DEFINITIONS

Customer: Individual that buys products or services.

Customer Loyalty: The likelihood of previous customers to continue to buy from a specific organization.

Customer Relationship Management: The management philosophy according to which the company's goal can be best achieved through the

identification and satisfaction of the customers' stated and unstated requirement.

Customer Retention: The assessment of the product or service quality provided by a business that measures how loyal its customers are.

Customer Satisfaction: The degree of satisfaction provided by the products or services of a company.

Information Technology: The set of tools, processes, and associated equipment employed to collect, process, and present the information.

Marketing: The social and managerial processes by which individuals or companies obtain what they need or want through creating, offering, and exchanging products with each other.

Marketing Strategy: The company's strategy that combines all of its marketing goals into practical results.

Implementing a Customer Relationship Management (CRM) System

INTRODUCTION

A report published by Gartner shows that the worldwide CRM market grew 13.7% from \$18B in 2012 to \$20.4B in 2013. They anticipate that CRM usage will increase to \$36.5B worldwide by 2017, which is a significant increase from the \$20.6B forecasted for this year. However, research also suggests that 80% of CRM implementations fail (Rowley, 2002; Muhmin, 2012; Nguyen & Mutum, 2012). Although there has been extensive research into CRM implementation and why it often fails, studies predominantly concentrate on the technical performance of the implementation (Payne & Frow, 2005; Xu & Walton, 2005; Cox 2013), or data migration issues involved (Manjunath, Hegadi & Archana, 2012; Canter, 2013). Therefore, the purpose of this study is to research CRM implementation and the challenges involved in such complex implementations.

This paper will start by exploring the benefits of CRM systems and why companies decide to implement them. We will review the literature on the challenges that companies face during implementation and then we will examine a real-life implementation case study. Our conclusions will provide academics and practitioners with a clearer understanding of the CRM implementation and will summarise the main aspects that need to be taken into consideration during such complex implementations.

BACKGROUND

Clemons (2000), defines CRM from a customer's viewpoint and suggest that in essence a tiny proportion of a company's customers will generate the bulk of its profits, "identifying, collecting and keeping these clients is the very essence of customer relationship management" (Clemons 2000:25). However, according to Krauss (2002) a CRM implementation and strategy can only be deemed successful only if it can actually improve customer loyalty. One of the main reasons for failure is the reluctance to put CRM and the customer at the heart of the company. Girishankar (2000) proposes that for CRM systems to become successful companies must take a holistic approach to their implementation.

Research claims that corporate structure, employee involvement and management support are the key factors for the successful implementation of a CRM system (Galbreath & Rogers, 1999; Lindgreen, 2004; Pinto & Rouhiainen, 2001). Companies need to be connected and open to communication while management must be de-centralized and encourage subordinates to innovate since often employees are the ones that can steer the vision of a CRM system. A good project leader will set out a clear mission on what the CRM system will achieve, gain management support, schedule a clear implementation plan, communicate frequently with the end user, recruit

a successful well trained team, train employees successfully and gain end-user acceptance once the implementation is finished.

Siddiqi, Akhgar, and Wise (2011) agree that a clear report must be produced and analysed before a formula for success is produced because success depends highly on how the company views and aims to use the system in the first place. Organizations must choose between a customer focused system that allows a personalized service, or a company focused system that is mainly used for analysis and forecasting. It is likely that using a “soft” approach to the system, targeting specific customer in tailored ways will bring the best financial gains, and therefore employee motivation and support. Furthermore, Kotorov (2003) suggests companies must view CRM as a strategy rather than a technology solution.

Payne and Frow (2005) and Parvatiyar and Sheth (2001) believe that the lack of expertise and communication from IT departments is the most important factor in failure. Payne and Frow (2005) state that due to marketing and IT departments having no previous link, the lack of communication can lead to migration problems. This is a continuation of Parvatiyar and Sheth (2001) model, who suggest that in an enthusiasm to implement CRM, companies can hastily pass the implementation on to the in-house IT department. In order for a CRM implementation to be successful, employees must be involved in the design since the ineffective communication between IT and other departments leads to the implementation of a technically biased system, rather than one with wider benefits (Lindgreen, 2004; Pinto and Rouhiainen, 2001).

Xu and Walton (2005) state the reason for most failures is the lack of technology advancements and companies not pushing for greater analytical power from the systems. They believe that by being comfortable with what the providers currently offer, they are not harnessing CRM to its full potential. Cox (2013) agrees with this, believing that the technology on many systems is not being used to its full potential. However, he suggests that

this is due to the technology selection process, rather than the lack of potential technology. If a company selects an inferior product that does not benefit the employees then there will be issues.

Once the correct solution for the company has been picked, migrating data and information from previous systems is a large part of the implementation. Kostojohn, Paulen and Johnson (2011) are one of the few who studied data migration. They argue that correct migration can add tremendous value. They state that data migration does not cleanse data, and merely drags everything across from the old systems. In order for any implementation to be successful, data must be cleansed and organised. Similarly, Epicor (2005) emphasises the importance of thoroughly cleansing any data and an effective way to achieve this, is by employing data-administrators or specialists to help with the removal of duplicates.

Alongside the need for clean data migration, Kostojohn, Paulen and Johnson (2011) explore the need for adequate training. They state that in order for CRM to succeed, employees must be encouraged to use the system. This is a continuation of Reinartz, Krafft and Hoyer’s (2004) research that encourages relevant, well-planned and effective training that rewards employees for engaging in CRM activities. Becker, Greve & Albers (2009) also linked training directly to customer retention rates. Their research is one of the few that directly links components of the implementation plan to the outcome and success of a CRM implementation. They state that ineffective training will have a direct impact on the success of the system. Similarly, Zablah, Bellenger and Johnson’s (2004) research proposes that training can be used as a way to push companies’ strategies onto its employees. In order for implementations to prosper, training must be used so that all employees know how the company wants to use the system, its core principles and how it will benefit the customer and themselves.

There are limited case studies of CRM implementation that use literature and models to define success. Bull (2003) studied the implementation of a CRM system using the company ELMS as a

case study while Piskar and Faganel (2009) used a real-life case study of Sanolobar that offered direct insights into many of the problems faced during a CRM implementation.

The first issue with Sanolobar was that the IT managers had a clear vision of what they wanted the CRM system to achieve; namely to meet global competition and respond faster to market changes. This however was not explained clearly to their employees. Also, the company's manager saw little need for change while the employees had no previous knowledge of CRM systems so explaining the benefits to them was difficult. Piskar and Faganel (2009) state that the project manager plays a very important role in a CRM implementation. In this case the manager had no prior experience of a CRM system which led to a number of misjudgments and implementation errors.

Similarly, in the case study reported by Bull (2003) the manager lacked experience to produce a necessary evaluation of what type of CRM system the company needed. The lack of a strategic trained manager, led to the IT department working on an ineffective system which overstretched them and essentially led to the company not being able to use the CRM system in the desired way. Bull (2003) also explained that ineffective training had a knock on effect when striving to get employees on board with the CRM strategy. This created a fear of the CRM system within employees who now saw it as a cost cutting exercise. It was lack of communication and clear training that caused these issues.

MAIN FOCUS OF THE ARTICLE

Qualitative research has often been criticized for not being guided by theory in its development. However Mertz and Anfara (2006) disagree with this, suggesting that combining both the theory and the researcher's experiences can only benefit the research.

The knowledge gained through qualitative investigations is more informative, richer and offers enhanced understandings while the holistic nature of the research means that any question or answer can be explored and then analysed. Tewksbury (2009) states that qualitative methods gather how people understand, experience and operate within a certain parameter.

In order to gain maximum credible qualitative data the authors decided that conducting interviews was the best method. There are three types of interviews: unstructured, structured and semi-structured. Bloom and Crabtree (2006) suggest that no interview can be fully unstructured, but inevitably arise from the participants' reactions and environment. Structured interviews are particularly suitable where it is necessary to capture precise data, and correspond more to quantitative research. Although they tend to be quick to undertake they place a rigidity that is not beneficial. Our research has no use for pre-established categories; and as such structured interviews did not fit the research. We therefore decided to use semi-structured interviews.

Having established a semi-structured method, the authors were keen to collect data that was not biased and therefore elected to use the literature review to formulate the approach. In doing this, the authors split the question structure into sections:

- **Technology:** The authors used Payne & Frow (2005), Xu & Walton (2005), Parvatiyar & Sheth (2001) and Kostojohn, Johnson and Paulen's (2011) research to develop questions. The main line of inquiry was to establish if the product was the correct one for the company and offered everything that the participants needed.
- **Leadership/Communication/Structure:** The questions in this section used the research of Galbreath and Rogers (1999), Lindgreen (2004) and Pinto and Rouhiainen (2001) as basis. They aimed to understand the importance of effective leadership and

how a company's structure plays a part in the implementation.

- **Taking an Holistic Approach and Personal Views:** This section concentrated on the motivation of the employees and how the company uses the system based on the research of Kotorov (2003) and Girishankar (2000). This part aimed to explore the employees' perceptions about the system and how it was used.
- **Training and How This Affected Motivation:** Throughout the literature, the importance of training was prominent (Reinartz et al. 2004; Becker, Greve & Albers, 2009). The questions within this section aimed to explore the training offered; how it was tailored to individuals and the effect it had on motivation to use the new system.
- **General:** The last three questions aimed to sum up the interview, working chronologically on the most important parts of the implementation from an employees' perspective.

We interviewed 10 people from a technology company that for anonymity purposes we will be referring as Company X. Table 1 shows the interviewees' codes and job titles. Once the interviews had been completed and recorded the

Table 1. Interviewees' details

Code Name	Job Title
Participant 1	Operation Support
Participant 2	Software Support
Participant 3	Software Support
Participant 4	Technical Support
Participant 5	Operation Support
Participant 6	Software Support
Participant 7	Software Support
Participant 8	Operations & Technical lead
Participant 9	Technical Support
Participant 10	Software Support

authors transcribed them. The authors had already developed an understanding of the main issues with CRM and therefore transcribing the data allowed clear and thorough analysis.

King (2012) states that the choice of method of data analysis needs to be guided by the methodological position of the piece of research, in such King suggests that template analysis encourages the researcher to be explicit in their analysis as every conclusion can be traced back to the research. Template analysis, in essence gives the researcher a way of ordering the data into set codes. The authors used the initial five sections discussed above (Technology, Leadership/Communication/Structure, Taking an Holistic Approach & Personal Views, Training and How This Affected Motivation, General) in order to prepare the data. Once an initial analysis had been conducted the researchers were able to update the codes and analyse further. Crabtree and Millar (1999) suggest that by using a second set of codes it decreases the risk of missing valuable data, and allows the researcher to look beyond the initial codes.

SOLUTIONS AND RECOMMENDATIONS

Company X is a technology company and in 2013 they undertook the decision to change the company's CRM system from System A to System B (for ethical reasons we will be using code names for the systems). The UK was used as a tester region and System B was implemented as a pilot in this region. Similarly to many other companies Company X does not use System B as a sole CRM system which means that they also use other management and forecasting tools.

Success of Implementation

Often it is challenging to understand the intangible benefits that CRM systems offer, thus it is very difficult to measure their success. In order to discover how effective Company X has been,

the authors will use the employee's reaction to the question how successful has the implementation been? Participant 1 believes "it has gone very well" Participant 2 agrees, stating that "everything ran quite smoothly". However, Participant 3 and Participant 4 are more negative suggesting that "it wasn't successful in the slightest, too slow and buggy" and "not successful at all" respectively. It is interesting that the rest of the participants suggest a change in opinion overtime, Participant 5 suggests there is "room for improvement", Participant 6 that "I wouldn't say it was unsuccessful, it certainly wasn't without fault" and Participant 7 that "Overtime it is becoming more successful". These varied answers suggest that there were ways in which Company X could have improved the roll-out and the following analysis will decipher the most important parts.

Leadership

Throughout the literature a strong emphasis has been placed on having a strong leader to guide the implementation. Pinto & Rouhiainen (2001) state that a good project lead will ensure that communication is frequent with the end user. It is interesting that when probed on who was leading the implementation only Participant 4 & Participant 8 had an idea of who was the leader whilst the rest were "not aware" of any leadership. System B lacked a clear focal point from the outset, and from the employee's point of view, this instantly placed strain on the implementation.

Selecting the Solution

Xu and Walton (2005) state that if a company selects an inferior product that does not benefit the employees then this could potentially create a lot of issues jeopardizing the successful introduction of the system. This is evident in our case with participants often unhappy with the features offered or the technical performance of the system. In every interview there were references to changing certain aspects of the CRM system to enable

it to be more effective for employees. Over half suggest the need for "offline capabilities", whilst Participant 3 and Participant 7 talk negatively about the "lack of personalised features that make the system unique to each user". However, the lack of functionality is not as serious as the usability and performance issues. Participant 6 describes the system as "excruciatingly slow", with simple tasks taking "up to an hour longer per day" and Participant 2 explains hang-time of "up to 15 seconds loading per page". It is the usability of the system that is hindering the successfulness of the implementation and Participant 9 suggests that the system's inconsistency means that they "never actually want to look at it".

Employee Involvement

One of the main reasons for the technical issues is the lack of involvement from employees who use the system daily. Parvatiyar and Sheth (2001) state that although technical workers may build a system that is technically sound, it may not be effective for front-line employees. Participant 2 recognised the lack of involvement as a "big failure". Overall the front-line employees feel that if they had been included more in the design the implementation would have been more successful.

Furthermore, six months into the project the leadership team decided to take some of this feedback on board and set up an Ambassador program. In essence it was a selective group of end users who were given extra training and guidance on the system. The process would work two ways; firstly the developers would gain valuable insight and feedback, and secondly to create a taskforce of skilled users who act as advocates. Employees were shown "functions that were coming, however these were not available so it was difficult to get enthusiastic, felt that queries were being listened to but there was no improvement". It is interesting that when asked what were the main issues of the implementation Participant 5 stated that "I would want more input from the people on the ground, people who use it every day" and Participant 4

stated that “I would want a seller task force, who are the people who are going to be using it, and what do they need in the system. I would ensure that they were fully trained and became advocates.” It is worrying that although that the new system was set up to “spread the word” (Participant 8) six out of the ten participants were “not aware” that it existed. This would suggest a lack of communication throughout the project.

Communication

Galbreath and Rogers (1999) suggest the need for the company to be open to communication and Bull (2003) blamed the fear of the CRM system in their study on a lack of communication. When asked whether there was communication, all but one participant recognised that emails were sent regularly; the issue came with the quality of what was being sent. Participant 3 stated that they “felt that these were put in technical language rather than in a way that we could use” and Participant 7 felt that “answers were difficult to find”. Participant 4 described the dangers of giving communication that employees cannot relate to: “there were so many updates and bug fixes that you lost interest and didn’t take them seriously. Motivation was affected and it was used as an excuse not to use it (System B)”.

Managerial Support

Kotorov (2003) states that in order for an implementation to be successful it needs to have support from the highest echelon in the company. When asked what they believed to be the main issues, Participant 9 stated “we need to be on the same page and we are not at the moment, from senior leadership right down to the bottom users”. Ultimately, sending out communication that is untruthful holds back the improvement of the product. Employees become unengaged and demotivated, feedback becomes muted, and essentially the system is used for what the developers have developed, rather than what suits the

employees. Participant 7 identified that they “do not think” there is any encouragement in using the new system and Participant 5 reported that “as long as it is clean, not fussed about System B”. This would suggest that at lower-manager level the system is not being accepted, and other in house systems are being used instead.

Heart of the Selling Process

Girishankar (2000) proposes that for it to become successful the company must place CRM at the heart of everything it does. In Company X’s case this would mean removing other in house reporting systems to leave one customer-facing tool. This is widely recognised by the interviewees as a major issue with the implementation. Within every interview each participant states the need for the system to become more “collaborated”. Participant 4 said “Company X has several other systems that marketing and sellers can use which means that we don’t get the main benefits out of a CRM”. Participant 2 suggests that, “coming from an organization where everything was inter-connected and there was one system that records all, to a place where you have 3 or 4 systems seems odd. I think there should be integration”. This affects motivation to use it, but more importantly affects benefits that the customer can receive. Ultimately Company X has created a solution that misses the fundamental point of a modern CRM system.

Company X’s Structure

In order for a CRM implementation to be successful the structure of Company X would need to be “open to change”. The participants had varied responses to whether change was needed, and ultimately how the new system compared to the old system A. Although Participant 4 believes that “System A was an outdated first generation and needed updating”, on the other hand, Participant 6 didn’t “know why we moved from System A”. This again links to the communication and leadership. If Company X had allowed every user to

know the reasons for change then the transition may have been smoother. In order to achieve success Galbreath & Rogers (1999) argue that a company's structure must encourage subordinates to innovate. In our case study it is evident that it is not the employees that need encouragement to innovate, but perhaps the company that needs to improve.

Training

The literature presents a strong need for the training on any new system to be extremely important and it appears that Company X have had real issues in this area. When asked to comment on the effectiveness of the training all but one of the participants talked negatively. Participant 7 stated "It was a waste of time, so I taught myself", Participant 9 "I didn't think we were trained enough, I wanted to use it but ended up being frustrated", Participant 2 suggested "the reason I did not know what I was doing is because the training was not great". Most importantly, Participant 6 linked the poor training directly to motivation "It's hard to get motivated about something you don't fully understand". Kostojohn, Paulen & Johnson (2011) and Reinartz et al. (2004) recommend that one way of improving training is to offer tailored guidance specific to employee's roles. Participant 3 recognised the lack of individuality stating that the training was just "several people on a webinar looking at an automated screen, no personalisation". Company X will need to improve this moving forward and use training as a way of engaging employees. They could use this to explain the need to change from System A and create a clear and consistent message to its employees.

Data Migration

A major part of implementations that often gets less limelight is the migration of data from the old system. It appears again that Company X had varying success with this. Participant 2, Participant 7 and Participant 1 suggest there were "no issues",

Participant 3 recognised there were "teething problems" and Participant 10 suggested that there were "initial issues that were all fixed". Participant 4 and Participant 6 however were affected massively by ineffective migration. Participant 6 argued, "data did not transfer across and deleted entries. I had to re-add opportunities" this added "a huge increase in time and frustration". Participant 4 stated "there were too many problems, when it first came across I stopped using the system due to the data being all over the place". This suggests extreme failure in parts of the migration with employees using this as an excuse not to use the system.

FUTURE RESEARCH DIRECTIONS

It is evident that although this research brings together various researches, the study of CRM is still relatively uncommon. CRM systems are continuing to grow and as the technological age advances, these systems will play a bigger role. Our case study is unique due to the size and scale of the project; which has brought up problems that perhaps would not be faced in smaller organizations. The authors would suggest applying the ten factors for success identified in this paper in other companies in order to further investigate the more important issues involved during CRM implementation. It will be useful and very interesting to conduct further case study analysis in companies of various size and various industries. The authors believe that CRM systems will be a vital part of the vast majority of businesses in a few years and therefore more research is needed to further understand these complex systems. It is disappointing that in a world where technology is so impressive; much of the power of CRM is being lost.

CONCLUSION

Through reviewing the literature and by contacting a primary case study, it is evident that there

are many variables that may influence the success or otherwise of CRM implementation. Listed and explained below are the ten key points that the authors believe must be in place:

- **The Need for Change:** The Company needs to have a genuine reason for implementing a system, which will benefit both the customer and the employees. This must be explained clearly to the people who will be affected.
- **A Beneficial Corporate Structure:** The structure of the company must be open to this change, and any communication that comes with it. It must have the resources in place, and it is beneficial if it encourages innovation.
- **Communication:** There must be clear and truthful communication throughout. This needs to be put in a language that can be understood by the whole company, allowing all levels of the organisation to establish a shared understanding.
- **Leadership:** A strong leader must be in place with accountability for the implementation. The leader will be experienced with CRM systems, know how to get the most out of them, motivate employees around them and create a solid technical team.
- **Selecting the Correct Solution:** The solution must meet the company's requirements, and add genuine value to what is already there. It must be tested thoroughly with a correct sample size, and must be able to work independently before any parallel running is removed.
- **Using as a Modern CRM System:** The solution must be placed at the heart of the company; it is to be used as the focal point for all customer interaction, adding benefit rather than analysis. The system must be inter-departmental, encompassing the whole organisation.
- **Employee Involvement:** Front line employees and end users must be consulted from the start and throughout. Feedback from the system users will be invaluable in order to know the way the system is used and what is really needed.
- **Top-Level Support:** The company's leaders must offer support and resources to the IT and development team. Their message must be one of resilience; this will filter down through the rest of the company. Timescales must be set to allow time for effective implementation.
- **Data Cleansing:** It is important to ensure before data is migrated to any new system that it is cleansed and data-administrators put in place. This will improve efficiency and subsequent employee support.
- **Training:** Effective training is a key aspect to any successful implementation. Training should focus on the usage and purpose of the new system in a companywide context. It is essential that training takes place on fully operating systems and is focused on the roles of the individuals participating.

It is important to obtain feedback from employees and where possible customers to identify further improvements to the system, taking it to its full potential. The benefits that CRM systems offer mean that customers should gain an improved service. By not harnessing constant improvement, success rates will fall. This research provides practitioners a general overview to the problems faced, and potential solutions to many issues.

We created a strategy or model that would allow practitioners a collaborated view to ensure future success in CRM implementations. The authors brought together the points found in the literature review, as well as in our analysis and findings in order to create ten factors that can help organisations to realise the full potentials of CRM systems. This is not available in published articles and in such, places a genuine need and importance for our study.

KEY TERMS AND DEFINITIONS

Case Study: An up-close, in-depth, and detailed examination of an organization.

Communication: The means of sending or receiving information.

Customer Relationship Management (CRM): Identifying, collecting and keeping clients.

End Users: The people who actually use a particular system.

Implementation: The process of putting a plan into action.

Leadership: Leading a group of people or an organization.

Training: The action of learning a new skill.

INTRODUCTION

Many organizations are implementing electronic Customer Relationship Management systems in an effort to secure and maintain competitive advantage. Developing and enhancing long-term relationships with customers requires using quality data about the customers. Unfortunately, many e-CRM systems have failed to achieve their objective because of the issues associated with data integrity (Chen & Ling, 2008). The integrity of the data used to make decisions regarding customers in an organization affects the quality of the decisions made.

Protecting data integrity is challenging particularly in big organizations. The challenges associated with data integrity are increased by the complexity of the current business environment. Furthermore, marketing strategies and programs usually change rapidly in organizations (Fan, W. et-al, 2011). Therefore, to get the most out of relationship marketing, the customer data has to conform to the standards in a given industry. In addition, the data should be time stamped to make its validity clear. In addition, the data should be complete and accurate by having all the required values correctly entered. Finally, it is important for the customer data to be consistent (Chen &

Ling, 2008). This means that the data values should be aligned across all systems in an organization.

BACKGROUND

Various studies have been done before by a number of scholars as far as the quality and accuracy of data in e-CRM systems are concerned. Research on optimising the value of e-CRM application in E-commerce aims at determining the responsive prospect of customers to E-commerce applications (Ahmed, Maati & Al Mohajir, 2015a). The study revealed that customers often become frustrated if the e-CRM system is redundant and incapable of meeting their needs and expectations. A revelation from the study is that quality of data goes far deeper to include ergonomic relationships (Ahmed, Maati & Al Mohajir, 2015a, pg. 150). As such, any design or approach to improve data quality must measure and ascertain that the implementation of an e-CRM system meets the ergonomic conditions. With the study aiming to determine whether potential customers can respond to the e-CRM application, the researchers established that culmination of the application should deal with all customer-related issues. Such issues include customer services facilitation, sales and

marketing, and field support (Ahmed, Maati & Al Mohajir, 2015a, pg. 152).

In addition to data quality issues, companies embracing e-CRM systems face difficulties in developing effective technological infrastructure considering the limited time and resources (Ahmed, Maati & Al Mohajir, 2014, pg. 214). A recent study revealed that 66 percent of loaded orders are discarded before checkout, and only 5 percent of customers who visit organisations' online stores become customers (Ahmed, Maati & Al Mohajir, 2014, pg. 214). The aim of the research was to show that E-CRM is not limited to internet data but includes other devices such as phones, set-top boxes, pagers and so forth.

In another research by same authors, Ahmed, Maati, and Al Mohajir on how to improve the E-CRM intelligence by using CRM data analytic tools such as OLAP, data mining and web analytics, it was established that CRM analytics tools not only contribute to exceptionally productive customer relationship as regards sales and service delivery but in the development of adverts, planning, and the analysis of customer data as well (Ahmed, Maati & Al Mohajir, 2015b, pg. 7). As such, it is evident that real experience for an online client is dependent on an intelligent, concise, and convenient application.

In another study, authors targeted to a larger extent the problems resulting from formatting errors, data inconsistencies and lexical errors. A good example is the token based and attribute selection algorithms (Z. Yuhang, 2010). The algorithms allow for eliminating duplicate records data in databases. The algorithms' implementation is in such a way that users pick on the source and the preferred mode of repair. This functionality is realized courtesy of the application of distance function on the attributes that are unclear. In these algorithms, the repair time and progress is visible (Z. Yuhang, 2010). Yuhang suggested a new technique for cleaning using the frequency of words appearance. In clustering texts, C- cluster-

ing algorithms were used. It was a very effective technique in the reducing of tendencies of doing a mistake whenever a word that is rare is to be filtered (Nguyen & Mutum, 2012). With the help of the open source tool called Febrl, new algorithms and techniques for record linkage can be developed. It possess the ability to allow for varied formats of files and has a number of methods for encoding.

Problem Statement

CRM systems benefits organisations in a number of ways. The systems enhance coordination of internal processes and organizations' responsiveness to customers' needs. Data integrity is however an issue of major concern as far as e-CRM systems are concerned. In the current business environment, data is available from a lot of sources (Chen & Ling, 2008), in large quantities and huge complexities. According to a recent research by Bluewolf Consulting, data quality is a major issue of concern in e-CRM systems. According to the survey conducted by Bluewolf Consulting, 38 percent of the respondents were not confident in the accuracy of their instance's data.

A different research revealed that data quality problems cost an organization around \$ 100 per dirty record. The \$ 100 per dirty record includes costs such as the cost of printing and mailing to bad address, the losing disgruntled customer, sales conflict over the same lead and incorrect marketing segmentation and personalization. It is also important to point out that bad data is one of the three reasons why CRM projects fail. This is because bad data results in misleading, incomplete and confusing information. Data quality issues are therefore important when implementing e-CRM systems and can lead to limited acceptance or outright failure of the systems if measures are not put in place to enhance data integrity (Vitt, 2014). In this paper, proposed framework and algorithm for enhancing data quality in e-CRM systems is presented.

Literature Review

The goal of integrating business intelligence systems with E-CRM tools and techniques is very valuable to organizations today. It is due to the fact that this integration allows organizations to gather information on the customers, by applying sophisticated tools on the available data. This information can be accumulated from various media channels or points of contact that can be used as a communication node. These communication nodes are usually inclusive of the organization's contact number, websites and several other online forums that enable live chatting, direct mails, advertising materials and social media. Hence, the business intelligence systems are used to enhance the applications of the CRM systems by making use of datasets, which contains the customer's background and information such as; customer's personal information, purchase records, buying preferences and other concerns, to aid in decision making (Batenburg & Versendaal, 2007; Botha, Bothma, & Geldenhuys, 2008).

Therefore, the audacity of the E-CRM applications to acquire a robust system that assimilates such massive customer data, while also delivering the interactive tools to make the business process much more efficient and automated requires the integration of business intelligence systems. Hence, in an aftermath several E-CRM systems integrated with the business intelligence systems have been designed to accommodate the organizational needs (Busaidi, 2013; Chen & Lin, Enhancing the relationship benefit to develop relationship value, 2009).

Since the conceptual framework of integrating E-CRM and business intelligence systems, it has become the most robust technology related topic. In accord with the economists, CRM has not been a new notion, in fact with the current development and advancements in its application by integrating information technology CRM has extended more practically. The use of E-CRM is now done mainly for the marketing purposes to infuse the goal of taming the long term sustain-

ability of the customers by wandering away from the product-centric marketing services is a key driver that is profitable for the organizations. However, the use of business intelligence systems can make E-CRM more effective by tailoring the organizations decision on a particular product or service, thus boosting the customer portfolio (Chen & Ling, 2008).

With the increased competition circumventing the global industry, the need for E-CRM systems is getting a lot of cool. According to many organizations, the E-CRM systems must be designed to refine the organizational operations from top to bottom mainly focusing on the organizational endeavors incorporated in all the departments. It is noteworthy that the integration of business intelligence systems and E-CRM have aided in the manufacturing process, product testing along with its assembling, purchasing, and billing. Thus, an E-CRM system has become more effective and is beneficial for almost every organizational department, such as; human resources, marketing, sales and engineering (Chua, 2011; Fjermestad & Romano, 2006).

However, the integrated system have increased the complexity of E-CRM applications as the market competition has been escalated and organizations searches for sophisticated techniques that includes deep data mining of the customer data that is retrieved from all the touch points of the customer to accomplish their target. The accumulated data allows organizations to create and enable the holistic view of their customer profile (Anderson & Kerr, 2002). Moreover, the additional benefit to the organization is that it is now proficient at determining its target customers and therefore, predict the trends of their future purchases, which allows them to alter their marketing strategies accordingly (Horwitz, 2014; Jones & Ranchhod, 2007).

The integrated business intelligence and E-CRM systems have created an opportunity for the effective approach that seamlessly interlinks the sales, marketing, customer service, support and other operations concerned with customers.

Hence, the integrated system is centralized to keep important and profitable customers remain dedicated to the organization with reduced cost, increased quality and high revenues. Thus, the modern customer relationship management concept was shaped and motivated by the notions of quality management. In a lot of organizations today, E-CRM is considered as a technological solution that forms up an individual database and empowers automation in sales and marketing strategies and operations of the organization in order to improve their focused efforts (Raab, Ajami, V., & Goddard, 2008).

From customer's point of view, the E-CRM systems offer customization and ease of implementing transactions irrespective of the type of channel used for the organizational and customer interaction. A lot of businesses have realized the standing worth of business intelligence systems and E-CRM with its potential to assist the organization's goal and endure a striking competitive edge in the global competitive market. Due to various, yet frequent alterations and variations in the global environment and competition, organizations cannot compete constructively with inconsequential advantages and tricks that can easily be replicated by the competing firms (Gosney & Boehm, 2000). Hence, they need something new and innovative to deal with. The integration and implementation of business intelligence systems and E-CRM is an opportunity to increase the advantages for the organizations and enable them to focus more on the development of actual relationships between

them and their customers. Successful organizations always deliver and cater for their customers' needs. In general terms, the integration of business Intelligence systems and E-CRM tends to provide a futuristic approach for the organizations by improvising their decision making capabilities (Peppers & Rogers, 2011).

Methodology

The E-CRM systems when integrated with the business intelligence systems provides ubiquitous features that have the ability to deliver sources of customer credentials at much lower costs than the traditional network technologies. In an organization, the E-CRM systems can be used to hoard, store, preserve, and distribute customer knowledge on a particular product or service. However, it is noteworthy that the effective administration of the information plays a very important role in using E-CRM, as it can be used for product modification, service and innovation, while keeping under consideration the views of customers (Lamb, Hair, & McDaniel, 2011).

To improve the business process it is very much essential to first improve the quality of the accessible data as depicted in Figure 1. However, to improve the data quality a proposed framework and algorithm should be implemented. The following section discusses the framework and algorithm that can improve the data quality for E-CRM systems.

Figure 1. The flow chart to improve decision making skills of an organization

Figure 2 shows the proposed data quality framework that can be used to enhance the quality of data for e-CRM systems. First, the system has mechanisms in place to eliminate user errors. In alleviating user errors, the proposed framework has the capacity to flag suspicious or questionable records by comparing the various data values. Customers may at times participate in submitting wrong and misleading data either knowingly or otherwise. To flag such data as suspicious, the proposed framework incorporates data mining tools that can compare and analyze data values with the aim of detecting abnormal data values. It is difficult to recover data integrity once it is compromised. As such, the data quality framework incorporates systematic safeguards that counteract and prevent dirty data from entering e-CRM systems.

The second step in the data quality framework is the data capture process improvement. An

organization can capture its customers' data at many points of contact such as SMS, E-mail and telephone conversation. It is important for the organization in question to ensure that the process of capturing its customers' information is efficient and error free. This can be achieved by identifying and profiling various channels that customers use to interact with the organization (Chen & Ling, 2008). Each channel is then treated with a customized solution that enhances data quality in the channel. Data capture process improvement should also entail standardization of data at each channel to ensure consistency and eliminate data duplication (Batenburg & Versendaal, 2007).

The third step in the data quality framework is data standardization. Standardization involves creating structure in unstructured or semi structured data to ensure that the collected customer data conforms to business rules and system standards (Chen & Lin, 2009). The fourth phase

Figure 2. Data quality framework

in the framework is data correction. The data correction phase entails correcting customer data to ensure that it conforms to its definition, value domain and range. It is also in this phase that the missing value algorithm is defined (Powell & Childerhouse, 2010).

The fifth phase in the data quality framework is data profiling. An organization should know the source and various attributes associated with its customer data. This will enable the organization in question to select the most effective cleansing algorithms and functions that can enhance the quality of the data. The sixth phase in the data quality framework is data unification (Nguyen & Mutum, 2012). In this phase, the new customer data is matched with the existing data in order to establish a unique identity across an organization. The process entails identifying similar data within and across data sources and appending new data or providing missing data to enhance the quality and value of the data (Nguyen & Mutum, 2012).

The seventh phase in the data quality framework is data integration. The main challenge in the implementation of e-CRM systems is that wide range of separate CRM applications and transactional systems that hinder an integrated view of customer data. As established by Fjermestad and Romano, there is an inadequate integration of operational e-CRM systems (Fjermestad & Romano, 2006). As such, system managers have to cope continually with a vast number of e-CRM applications. It complicates the attainment of high sales management because consumer attendants are unable to find the required information about customers. The study also demonstrated that there is an inadequate integration of various data sources, thus making each product to have its unique customer database (Fjermestad & Romano, 2006).

In most organizations, customer data are usually stored in marketing databases. It is however common to find customers interacting with various departments in an organization such as technical support and shipping departments on different occasions (Chen & Ling, 2008). The resulting

interaction may therefore end up in different databases across the organization. It is thus vital to avail all the pieces of customer data to the CRM system by integrating the various databases in the organization. This will ensure a total view of customer behavior in the organization. This is because integrating systems within an organization ensures that updates in one system automatically update other related systems.

After intergration, the customer data can then be used in e-CRM systems. It is however important to design the systems in a manner that allows for data augmentation. This entails incorporating additional external or internal data that is not directly related to the customer data in question in order to gain insight. The customer data can be combined with data from third parties in order to enhance understand of customers' behaviors (Chua, 2011). This can enable an organization to easily segment its customers in order to meet the needs of each segment cost effectively.

The final step in the data quality framework is the maintenance monitoring and cleansing. Maintenance monitoring and cleansing is important in ensuring data integrity. This is because achieving data integrity is not a one-shot effort. There is need for an ongoing vigilance. It is therefore important for an organization to put in place policies, processes and tools that will enable it to monitor and solve data quality issues in its e-CRM system.

Data Cleansing Algorithm

The organizational data on the website is usually not correct and outdated (Chen & Ling, 2008). This is usually due to duplicate record and misleading information. The front end of the system is designed using Java or any other web language, such as; PHP. The proposed backend system is designed using SQL for the database. The integration between the front end and the backend system completes the algorithm. Besides the storage, retrieval, and modification, data quality issues

also may arise in the implementation process. This is due to the lack of software technology, infrastructure, customer-centric strategy, and commitment from a corporation.

Generally, CRM software can enable business transactions, facilitate data mining and warehousing, create operational-centered databases, and provide marketing campaign supporting tools (Chen & Ling, 2008). However, different firms provide CRM software with different package specifications. Issues regarding the quality of data arise when a corporate, say an e-commerce site selects CRM software that do not meet their business specifications. Qualities issues also are common in the case of a defective infrastructure. The seamless E-CRM performance requires a well configured corporate infrastructure. Poor quality of data is prevalent in cases of meager network setup, storage capacity, data backup, and backlogged web servers.

However, with this proposed approach, the varying date formats in the fields of type- date are exploited. The date is used as an illustrative example, but this could be applied to all data input types with predefined predicates. Simply, this proposed approach is not limited to one single data type but the rest too even the higher in the precedence order of SQL server such as XML, datetime2, or date time offset (Vitt, n.d). Such is true as long as the algorithm for the define rules using Java programming model as graphical user interface (GUI) and SQL at the backend. If a user or operator merges two expressions having unique data types rules defining data type precedence specifies that lower precedence data type to be converted to higher precedence data type (Vitt, n.d). In regard to the illustrative example, problems faced include the realization of a normalized standard date format, disguised date values, varying time zones, differing abbreviations and different forms of separators between the date parameters. The flowchart in Figure 3 gives the flow of the suggested data cleansing algorithm.

Figure 3. The proposed model

Explanation of the Proposed Algorithm

In the proposed algorithm the user or the customer will be asked to fill in the details regarding the product or service quality. Moreover, the GUI shall be designed in such a way that it provides the clientele's personal information, such as the purchase history, the preferences and the comments of the customer on the product or services as this informatics are essential for CRM improvisation. The data inputted must not have a limitation of data formats, i.e., the proposed system must allow all data formats to be evaluated and used accordingly. The rules must be applied by an organization on the dataset to extract the useful information. These rules may include application data mining tools as well, such as: R-Programming, Weka and Rapid Miner. Additionally, these rules set by an organization will define that what sort information is needed by an organization to improve its processes. However, this is the most crucial part

of the system where rules are being made and set by the organization itself. The set rules will improve the data quality, if the right information is extracted from the data then and only then the quality of data can become better.

The extracted data is then stored in a database where series of functions can be applied on it inclusive of the sorting of data, data mining and other sophisticated tools to get the desired results. The applied tools and techniques will provide information on the basis of majority hits, i.e. it will provide with what majority feels about the product or the services. Hence, the proposed model can easily help in improving the data quality which could further improve the business process and decisive skills of an organization. The algorithm proposed by Wing Ning Li, Johnson Zhang and Roopa Bheemavaram sorts the data to make it more efficient. The sorting algorithm determines if the two inputted records are related in any way or not with the any other records and thus partitions the records based on its relation (Li, Zhang,

& Bheemavaram, 2006). As the data depicted in Figure 4 is sorted out using the algorithm and the result is illustrated in Figure 5.

Similar, Algorithms have been introduced to improve the data quality and can be efficiently used by organizations to increase viability of their ECRM processes.

RESULT

The proposed model will enhance the data quality as the accurate information is extracted from the database and is analyzed to enhance the customer relationship with the organization. The tagged data will be accessible to the organization for decision making and improvise their product or service quality. Moreover, the E-CRM when integrated with business intelligence also provides additional features that can be benefited from. These features of the proposed system will include following benefits;

Figure 4. Different fields of data indicated by record no. and set no.

RecordNo.	Key 1	Key 2	Key 3	Key 4	Set Number
R1	C1K1V4	C1K2V10	C1K3U30	C1K4U31	1
R2	C1K1V4	C1K2U2	C1K3U3	C1K4V2	2

R12	C1K1V23	C1K2V1	C1K3U14	C1K4V5	12

Figure 5. The data records sorted out in a database

Automation in Marketing Processes

The integration of business intelligence and E-CRM systems implement automated capabilities to easily manage the order of repetitive tasks and enhance the marketing exertions accessible to the customers from the different stages of the production lifecycle. For instance, if a sales prospect is considered, the system will inevitably direct the marketing content via mail or social media in case to spin the sales, building a mature customer for the organization (Cunningham, 2002).

Automation in Contact Services Operations

This tool in the integrated system of business intelligence and E-CRM is designed to lessen the monotonous operations of a contact center agent's job. The computerized solution will include a recorded audio that helps in customer problem solving queries and distribution of information. Numerous tools are assimilated with the agent's desktop tools in order to manage the customer requests and bring down the call intervals, while simplifying the whole service process (Brink, 2009).

FUTURE RESEARCH DIRECTION

There already exists a couple of e-CRM technologies aimed at improving service delivery and interaction experiences between the companies and customers. For these to be achieved, both the companies and the customer personnel must have a fair interaction with the e-CRM system. The main focus of this paper was to realize a better interaction experience between the companies and the e-CRM system. The proposed framework and algorithm are aimed at enhancing data quality for e-CRM systems.

Another area that this paper adds knowledge to is on data integration and duplication. These two areas are new and continue to evolve, and hence less regard is given towards their implication. Only a few studies on the issues are given address perhaps because of the faster rate upon which the integration is invoked. This is because, the more data is brought together; any e-CRM is likely to face a range of data issues regarding quality that require attention.

CONCLUSION

For businesses that have adopted e-Business, it is a vital business function to enhance the quality of their services. This can be achieved by using high quality data in their e-CRM systems. Data quality improvement allows for consistent data types with the help of an implementable framework and algorithm that can go a long way in ensuring data quality in e-CRM systems.

KEY TERMS AND DEFINITIONS

Business: Business environment which operates in Intelligence of E-CRM.

Data Quality: The level of quality of data from E-CRM application (this is our subject).

E-CRM Systems: Electronic Customer Relationship Management system encompasses all the CRM functions with the use of the net and organizations environment.

Intelligence: One of the features that have E-CRM systems and their process.

Organization: Place where operator Intelligence of E-CRM systems such as institutions and companies etc..

Process: All about related of business generated from Intelligence of E-CRM application.

Relationship Management: Strategy in which a continuous level of engagement is maintained between an organization and Intelligence of E-CRM application.

Optimizing Cloud Computing Costs of Services for Consumers

C

Eli Weintraub*Afeka Tel Aviv College of Engineering, Israel***Yuval Cohen***Afeka Tel Aviv College of Engineering, Israel*

INTRODUCTION

Cloud Computing (CC) typically deals with organizations using computing services, communication and web applications. The National Institute of Standards and Technology (NIST) defines CC as a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (for example networks, servers, storage, applications and services) that can be rapidly provisioned and released, with minimal management effort or service-provider interaction. Cloud computing targets four main groups of organizational customers: private, public, community and hybrid. Customers choose their CC provider which gives them maximum value in minimal costs. This paper examines users' motivations in choosing their pricing model; certain customers are looking for best value, others looking for least cost while others look for a combination of both reasons.

This research reviews the main motivations and obstacles to adopting the cloud technology by companies, and develops a cost model for optimizing the consumer costs. Providers currently offer software services as bundles consisting of services which include the software, platform and infrastructure services. Providers also offer platform services bundled with infrastructure services. This bundling policy is likely to change in the long run since it contradicts economic free market rules and competition conditions, causing an unfair pricing model and locking-in consumers

to specific service providers. A famous example is the Israel telecom revolution where the introduction of competition in 1995 led to an extremely high subscriber growth rate, one of the highest in the world. As of 2014, penetration stands at approximately 125% (The Israel Ministry of Communication, 2016). Vendor lock-in is a major barrier to the adoption of cloud computing, due to the lack of standardization (Opara-Martins, Sahandi, & Tian, 2016). This research assumes that in the future market forces will push providers to act in a free competitive market, in which consumers are free to switch their services among providers. The proposed model is aimed at the potential customer who wishes to find the optimal combination of service providers which minimizes his costs. The objective of this paper is proposing possible strategies for implementation of the model in organizations, optimizing consumers' costs.

BACKGROUND

Comparing CC pricing models is a complicated task due to variance among providers' services and structure of tariff tables. Researchers found that cost saving is the strongest incentive for organizations considering CC adoption (Yung-Ming & Chia-Ling, 2012). CC services are usually sorted to three groups: SaaS (Software as a service), PaaS (Platform as a Service) and IaaS (Infrastructure as a Service), each service belongs to a specified group, and is offered for specific prices.

DOI: 10.4018/978-1-5225-2255-3.ch141

There exist two main pricing models. Pay-per-use is the most used model, in which the consumer is charged a fee for a used unit in a specified duration. The unit used may be a certain computing unit of hardware, software or application. Fixed-price model, in which the user is charged for using a service unit for a fixed price, usually in periods of month or year. In the fix-price model consumers may consume an unlimited amount of unit resources, although in some contracts consumption is limited to a maximal amount which consumers do not intend to reach. In the fixed-price model consumers might be charged for resources they have not actually consumed. Al-Roomi, Al-Ebrahim, Buqrais, & Ahmad, (2013) surveyed pricing models, and classified them to three groups: fixed – in which the customer is charged the same amount all the time, dynamic – in which prices changes dynamically according to purchased volumes and market-dependent in which prices change according to market conditions. Lai (2005) claims that market competition powers using pay per use pricing model could bring efficient allocations of computing facilities. Weinhardt et al., (2009) illustrate that current trends in CC show an ambition to base pricing models on dynamic pay-per-use pricing models. In certain cases consumers prefer to pay a fixed price, ignoring pay-per-use model advantages which fit their exact consumption and might minimize their costs (Anandasivam & Premm, 2009; Pueschel, Anandasivam, Buschek, & Neumann, 2009). Wu & Banker, (2010) found that some providers offer pay-per-use pricing and leave some consumer surplus to the customers in order to be more attractive. Researchers explored cloud provider pricing models using cluster analysis and found common business models; first cluster includes niche providers who use fixed pricing, second cluster includes mass players using pay-per-use pricing models (Labes, Erek, & Zarnekow, 2013). A possible explanation of using fixed prices is lock-in situations prevalent among niche players' products. Lilienthal (2013) who compared costing

schemes offers a decision model which calculates financial trade-off with respect to the workloads.

Several researchers studied anomalies in consumer decisions. Lambrecht & Skiera (2006) identified fixed-prices biases in which consumers prefer a fixed price model although they would pay less on a pay-per-use tariff for reasons of budget confidence, and cases of consumers prefer a pay-per-use model paying more for operational flexibility. Koehler, Anandasivam, Dan, & Weinhardt (2010) also found that the insurance effect has significant influence on the fixed-price bias while the pay-per-use bias is influenced by the flexibility effects.

Several researchers state that providers use to offer free of charge services using lock-in strategies (Koehler et al., 2010). Researchers found differences between private and organizational consumers (Weinhardt et al., 2009). Most cloud services which are focused on private consumers are free of charge while organizational consumers are usually charged, and only some add-on services are free of charge. PaaS providers often offer their development tools for free. Walterbusch, Martens, & Teuteberg (2013) raise the awareness of indirect and hidden costs in cloud computing pricing models. They found that some providers try to attract customers by a low price per storage while charging hidden costs for data transfer. Chen, Han, Cao, Jiang, & Chen (2013) state that customers face difficulties in evaluating prices of cloud services, those difficulties are one of the main reasons preventing customers from adopting cloud services.

This paper proposes a pricing model which optimize customers' costs in a future cloud computing free-competition market, thus eliminating the above discussed market in-efficiencies.

MAIN FOCUS OF THE ARTICLE

Research literature in the CC pricing models domain names three competition barriers' features:

bundling of services, lack of transparency, and varying tariff structures.

Bundling of Services

Examining providers' pricing models as published in their websites (Amazon, 2016; Google, 2016; Microsoft, 2016) illustrates the phenomena of bundling services, where each provider offers only a couple of services while other providers offer their preferred services. Weintraub & Cohen (2015) introduce new definitions of two kinds of bundling: first is horizontal bundling, second is vertical bundling. In horizontal bundling a provider offers several services, all belong to one layer. For example Amazon EC2 offers several bundles each one is composed of the following components: CPU, ECU, memory, instance storage, and operating system. In such bundling situations consumers may not use their own operating system. In vertical bundling a provider offers services which belong to lower layers, in addition to the main needed service. For example Amazon offers SaaS services, in which the consumer is asked to choose the configuration of infrastructure he wants the software application to run. A consumer looking for SaaS services may not use a PaaS service such as his own operating system or an operating system he bought from another cheaper service provider.

According to Weintraub & Cohen (2015) consumers should be able to choose another IaaS provider instead of being forced to use the infrastructure services of the SaaS or PaaS main provider. Providers use to bundle services in ways that customers are unable to know the real prices of each service. Such a situation contradicts economic competition principles, causing an unfair pricing model when examining customers' optimal alternatives.

Lack of Transparency

Bundling masks the prices of services, in both situations: vertical and horizontal bundling. The

provider offers a tariff for the whole bundle without breaking it to its components' services, in a package deal. In such situations customers do not know the price of a specific service which is part of the bundle. Researchers found that public cloud customers receive no insight into the underlying IT infrastructure and have restrictive administrative rights (Walterbusch, Martens, & Teuteberg, 2013). El Kihal, Schlereth, & Skiera (2012) state that transparency of service costs in cloud computing is a key factor to popular wide usage by organizations. Blau, Neumann, Weinhardt, & Michalk (2008) propose a pricing model which includes incentives to providers who are willing to present the pricing components of their services and also the configuration of the technological implementation such as the assets consumed for each service. Improving transparency will be feasible by breaking bundles to component services so that a consumer may choose each service by comparison to competing providers' prices.

Varying Tariff Structures

A consumer wishing to compare a service offered by several providers may find it difficult to perform, sometimes impossible at all. The large number of cloud providers' services based on varying pricing schemes has led to complexities in cloud service selection (Rehman, Hussain, & Hussain, 2011). According to El Kihal, Schlereth & Skiera (2012) pricing models providers use different tariff structures; some providers such as Google charge separately for each service, and providers like Amazon and Microsoft offer predefined bundles of services. This situation is due to reasons such as services having different functionalities, computing resources having different technological characteristics, differences in service levels, differences in contract duration and differences in discounts offered for certain volumes. The variability of charges between current SPs does not give sufficient common ground for a simple comparison. The issue of tariff structure variability is intensified due to the usage of two

different pricing models: fix-rate pricing and the pay per use pricing which enable customers incorporate risk analysis and cash-flow considerations.

This paper proposes a pricing model in which the customer is free to choose service providers according to his own pricing preferences, composing the bundled services by his own. In the proposed model tariff tables are normalized to hourly time units. The model simulates situations in which consumers may install software or hardware components on multi providers' sites, optimizing consumers' total CC expenses.

SOLUTIONS AND RECOMMENDATIONS

Solutions

Cloud computing architecture is described in literature as consisting of three layers: IaaS, PaaS and SaaS, each layer performs certain functions and also supporting functions requested by upper layers. Weinhardt et al. (2009) introduced a framework of CC architecture, composed of three layers of functions; The *Infrastructure layer* – focuses on providing technologies as basic hardware components for software services. *Platform layer* - includes services which are using cloud infrastructures needed for their functioning. *Application layer* - consists of the human interfaces used by the organizations' end-users. Applications are running on cloud assets, making use of platform and infrastructure layers, managing underlying infrastructures for the offered service. For example a SP suggesting a SaaS product is also bundling into the product the PaaS and IaaS layers.

Using current cloud computing technologies, a certain provider may run an application using another provider's infrastructure, but in practice both providers are parts of the same organization (Zhang, Cheng, & Bautaba, 2010). Bundling practices used by service providers force customers pay for components they may buy cheaper from other providers. Paraiso, Haderer, Merle, Rouvoy,

& Seinturier (2012) state that in the future developers will plan their cloud applications enabling migration of services among multiple clouds. Velte, Elsenpeter, & Velte (2009) state that applications belonging to different layers will be run on separate geographical locations.

The business model proposed in this article enables implementing functionalities of a service provider interfacing the underlying layers by other service providers. This functionality puts two requirements on cloud architecture. First, the architecture should use open standards which enables interfacing between many components of many providers. Second, the architectures' building blocks should be loosely coupled. Implementation of those two functionalities enables connectivity among vertical and horizontal services, thus eliminating the bundling phenomena. Figure 1 describes the new suggested Cloud Computing Competition-enabled Architecture. Arrows describe services supplied by underlying layers. Rectangles describe computing services. A consumer looks for services of each one of three levels. Each provider may buy certain services from other providers. For example a consumer looks for SaaS services, he finds the cheapest SaaS provider, who also buys certain PaaS and IaaS services from other providers.

The inability to compare SP offerings is a competitive market failure which hinders not only SP competitiveness, but also the decisions of the customers. In an efficient market, customers should be able to easily compare all their options, and choose the best. Vendors will have to adapt their pricing models to standard schemes in order to improve their competitiveness. In the following, the proposed model suggests two pricing models in which service providers are competing for offering the best service to customers' requirements.

The Case Study Example

The simplest basis for comparing pricing schemes is using a ratio of Cents/Hour of usage. A more advanced pricing basis may include an addition

Figure 1. Cloud computing competition-enabled architecture

to the usage payments, periodical fixed payments for various services. To enable simple comparison of SP's Each SP base its offer on its in-house offering with complimentary services bought from its business partners. Also, when a SP buys another underlying service from another SP, s/he must pay not only for the service, but also for the administrative work and the interfaces between suppliers involved in the purchase.

This section describes a theoretical example of three SPs and their tariffs, and a consumer who chooses certain SP's based on his foreseen consumption. Following, an introduction of three pricing models which will make use of the data described in this section. Table 1 summarizes the customer estimated monthly requirements of hypothetic cloud services. All requirements are either in hours, volume or other specified unit.

The customer contacts three candidate SPs to get a price quote. The published tariffs of these SPs appear in Table 2. Each SP provides all the services using his/her tariff.

So, based on current practices bundled services per SPs would give:

- SP1 price per monthly usage: \$ 4038.40
- SP2 price per monthly usage: \$ 4220.80
- SP3 price per monthly usage: \$ 4964.00

Therefore, SP1 is the least cost provider (\$4038.40). However, the suggested model enables

Table 1. Customer estimated monthly requirements

Service Name	Requirement in Units	Units of Service
SaaS		
Data transfer	4,800	1 TB
Email services	4,800	1000 messages
Cloud search	1,200	1 search
Documents Mgt.	400	1 hour
ERP	4,800	1 hour
PaaS		
Operating system	1,200	1 hour
Memory	2,000	1 hour, 1 GB
Instance storage	2,000	1 hour, 1 GB
Developer support	480	1 hour
IaaS		
Relational Database services	1760	1 hour
Storage standard vol.	480	1 TB, 1 hour
Backup (GB)	2,000	1 GB, 1 hour

the consumer to set an efficient market price that further minimizes his/her expenses. This could take several forms depending on the main supplier of choice:

Hierarchical Pricing Model

Since fitting SaaS services to the customer is more sensitive to customer requirements this

Table 2. Tariffs of three service providers (Cents/Hour); example prices, assuming basic usage

Service Name	SP1 Tariff	Sp2 Tariff	SP3 Tariff
SaaS			
Data transfer	2	4	2
Email services	4	6	2
Cloud search	6	8	6
Documents Mgt.	4	2	2
ERP	100	94	120
PaaS			
Operating system	26	36	14
Memory	40	50	70
Instance storage	24	20	30
Developer support	6	8	4
IaaS			
Relational Database services	18	12	38
Storage standard vol.	34	30	50
Backup	40	56	40

model assumes that each SP maximizes its SaaS capabilities and look for purchasing the best combination of platform and infrastructure services that best complements its own offerings in these levels. Since SPs seek simple management of sub-contracted services, only one SP could be chosen for complementing the platform or the infrastructure level. The Platform SPs can also purchase infrastructure services. Also, when a SP buys another underlying service he must pay two fees: a fixed monthly sum of money for initiating, controlling and maintaining the connection to the other SP, and a fee for each executed transaction.

While SaaS is the highest level in the hierarchy, the computations start from the lowest level (IaaS) and progress through PaaS to the decision taken by the SP based on their SaaS and possibly sub-contracted PaaS and/or IaaS. In this example the IaaS total monthly costs (in \$) per SP are as calculated in Table 3, Table 4 and Table 5.

Table 3. IaaS monthly prices per SP for the example

Service	SP1 \$/Month	SP2 \$/Month	SP3 \$/Month
IaaS			
Relational DB services	158.4	105.6	334.4
Storage standard vol.	81.6	72	120
Backup	400	560	400
Total	640	737.6	854.4

Table 4. PaaS total costs (in \$) per SP for the example

Services	SP1 \$/Month	SP2 \$/Month	SP3 \$/Month
PaaS			
Operating system	156	216	84
Memory	400	500	700
Instance storage	240	200	300
Developer support	14.4	19.2	9.6
Total	810.4	935.2	1093.6

Table 5. SaaS monthly price per SP for the example

Service	SP1 \$/Month	SP2 \$/Month	SP3 \$/Month
SaaS			
Data transfer	48	96	48
Email service	96	144	48
Cloud search	36	48	36
Document Mgt.	8	4	4
ERP	2400	2256	2880
Total	2588	2548	3016

Thus SP1 is the IaaS provider of choice for the requirements of this customer.

Again SP1 is also the PaaS provider of choice for the requirements of this customer.

Finally, the SaaS total costs (in \$) per SP per month are as follows:

Here SP2 is the SaaS provider of choice for this customer.

The customer in this model would choose at each level the provider of choice for the requirements. Ignoring the fixed monthly sum of money for initiating, controlling and maintaining the connection between SP2 and SP1, SP2 is chosen for SaaS (\$2548, Table 5) and SP1 for PaaS (\$810.4, Table 4) and IaaS (\$640, Table 3).

The total cost per month would be the sum of minimum: $640+810.40+2548 = \$ 3998.60$

Assuming there is a fix monthly fee of \$60 for initiating, controlling and maintaining the connection between two different SPs in each two consecutive levels. The monthly fee of 60\$ is chosen as an example only, for model illustration, without limiting the generality of the model since comparing investment alternatives usually involve fix and variable costs, two components which the model includes. An additional \$ 60 per month would be charged for the connection SP2(SaaS) - SP1(PaaS), and no charge for the same SP1 between PaaS and IaaS. In that case, the total cost would be: $\$ 3998.60+60 = \$ 4058.40$.

Let F be the fixed monthly fee for initiating, controlling and maintaining the connection between SP2 and SP1.

If $F < 2588-2548$ the above policy would remain optimal with monthly cost of $F+3998.60$.

If $F > 2588-2548$ than Choosing SP1 to supply the three levels of service would yield:

$$640+810.4+2588=\$4038.40$$

Of course supplier selection decisions require sensitivity analysis (finding the impact of small changes in requirements) but the example here is just for illustrating the required computations.

The Simple Pricing Model

This model relaxes the assumptions about hierarchy and the need for simple management and control over sub-contracted services. Thus, in this model each SP offers the bundle of services that is composed of the minimal tariffs. The cost of sub-

contracting management and control is assumed to be a fixed sum per service per period. Thus, each SP supplies his/her own services if their tariffs are minimal. Otherwise they sub-contract other suppliers (as shown in Table 6). For example SP1 offers the services included in SaaS PaaS and IaaS (Table 1 column SP1 tariff).

The minimal tariff of each item yields total monthly price for the customer's requirements of: \$ 3663.2. In addition, the customer must contact the other two SPs to establish the purchases and track the transactions. Assuming a monthly cost per SP per service of \$ 60.00 for the administrative work of ordering, tracking and payment management yields:

Main SP1: $3663.2+8*60 = 4143.20$

Main SP2: $3663.2+7*60 = 4083.20$

Main SP3: $3663.2+5*60 = 3963.20$

Thus, Main SP3 is chosen with monthly expenses of: 3963.20, compared with the minimal cost SP, this is annual savings of \$ 902.40).

RECOMMENDATIONS

Three preconditions are required for effective comparison of pricing models. Service providers have to offer standard functionalities of their products, standardize tariff table structures and show all cost components thus having transparent tariffs. Providers should build their services according to open standards thus enabling connectivity among different services offered by suppliers.

Consumers should enhance the usage of current technologies which offers several applications in which they can compare products prices, for example ShopSavvy and ShopAdviser. Such applications will enable CC services comparisons easily. Consumer organizations should switch their CC technological architecture to use the new offered pricing models; starting with the hierarchical model and when possible moving

Table 6. Minimal cost supplier for each service

Service Name	SaaS Minimal Tariff	SP1 Sub Contract (Bald)	SP2 Sub Contract (Bald)	SP3 Sub Contract (Bald)
SaaS				
Data transfer	2	SP1	SP3	SP3
Email services	2	SP3	SP3	SP3
Cloud search	6	SP1	SP3	SP3
Documents Mgt.	2	SP3	SP2	SP3
ERP	94	SP2	SP2	SP2
Service Name	PaaS Min. Tariff	SP1 Sub Contract	SP2 Sub Contract	SP3 Sub Contract
PaaS				
Operating system	14	SP3	SP3	SP3
Memory (GB)	40	SP1	SP1	SP1
Instance storage GB	20	SP2	SP2	SP2
Developer support	4	SP3	SP3	SP3
Service Name	IaaS Min Tariff	SP1 Sub Contract	SP2 Sub Contract	SP3 Sub Contract
IaaS				
Relational Database services	12	SP2	SP2	SP2
Storage TB standard volume.	30	SP2	SP2	SP2
Backup (GB)	40	SP1	SP1	SP3

gradually to the second simple pricing model thus achieving optimal costs.

Governments and regulatory agencies should build technological infrastructures and economical ecosystems, to enhance completion among providers and forbid providers using monopoly and lock-in strategies.

FUTURE RESEARCH DIRECTIONS

Further research is needed for incorporating additional consumers' considerations such as preference of a fix-price model on a pay-per-use model due to risk aversion, and providers' impacts on consumers' biases in buying decisions. Further research is needed for better understanding the providers' considerations in the cloud computing market.

CONCLUSION

This paper proposes two cost minimization models for cloud computing consumers, (while keeping the published tariffs). Choosing one of the models depends on its similarity to the actual needs and conditions in the CC market. The first model is hierarchical; one supplier is chosen for each of the three layers (SaaS, PaaS, IaaS). The hierarchical model is easy to implement and also reduces customers' costs compared to the current situation. This model produces only a limited amount of services unbundling and only limited transparency of prices. The second model called the simple pricing model, enables high transparency and unbundling of services and further cost reduction. Implementing this model is more difficult since the control of various providers and services is more complicated. The paper also gives recommendations to all parties involved in the CC market: private and organizational consumers, service providers and government agencies.

KEY TERMS AND DEFINITIONS

Bundling: Product bundling is offering a package of several products for sale as one combined product. Bundling can be regarded as an unfair use of market power because it limits consumers' choices.

Cloud Computing: Cloud computing is the delivery of on-demand computing services over the internet on a pay-for-use basis, with minimal consumer setup efforts.

Competition: Companies compete each other over the same group of customers. Competition causes commercial firms to develop new services, giving consumers better services. The greater selection causes lower prices for the services, compared to a market with limited competition.

Infrastructure as a Service (IaaS): A cloud computing model in which the provider offers remote hardware and basic software services such as operating systems, database management systems and utilities.

ADDITIONAL READING

- Faniyi, F., & Bahsoon, R. (2015). A systematic review of service level management in the cloud. *ACM Computing Surveys*, 48(3), 1–27. doi:10.1145/2843890
- Hummaida, A. R., & Norman, W. (2016). Paton & Sakellariou, R. (2016). *Adaptation in cloud resource configuration: a survey*. Journal of Cloud Computing: Advances. *Systems and Applications*, 5, 7.

Platform as a Service (PaaS): A cloud computing model in which the provider offers software components such as compilers and debuggers which are used for application development.

Software as a Service (SaaS): A cloud computing model in which the provider offers software applications aimed for remote usage by

IT professionals and business users. SaaS applications includes applications such as CRM and ERP.

Transparency: Transparency of a cloud computing service is the ability of the system to provide visibility of the structure and behavior of a process. Transparency leads to consumers' trust in the supplied service.

C

Taxonomy for “Homo Consumens” in a 3.0 Era

Carlos Ballesteros

Universidad Pontificia Comillas, Spain

INTRODUCTION

Consumption is a basic human activity that implies a wide range of consequences: economic, psychological, environmental and social ones. Although it is true that consumption is one of the principal and most necessary engines for modern economies, there are important ecological and social costs in its practice. As human beings we are co-responsible for our consumption habits. We can no longer think that to consume is a free act that only implies ourselves and what can we afford. Through our lifestyles and consumption patterns we transform the world. Consumption can be seen in many different ways: from a liberal perspective nobody has the right to influence and be critical about your consumption but yourself: you have the freedom and the right to buy what you can/want/desire; from a reformist point of view, as a society, a consumer society is the best, the ideal society we can have, but it has some drawbacks that we can reform or correct; The sustainable side states that it is possible to move towards a cleaner (and a fairer) world with certain behaviours; Last but not least there is even a political viewpoint where consumption can be seen as a way to change the world. There could be also a radical position (also seen as destructive), or also an ascetic one, that pleads for a new relationship between the Planet and Humankind in a back-to-the-roots path.

It was Erich Fromm, in 1965, who was the first to call the human species *Homo consumens*, a term that evolved from *Homo sapiens* to denote how we devote all our efforts, beyond working from 9:00 to 5:00, to consume compulsively as a means to

sublimate our frustrations. In addition, Saad (2007) and Lipovetsky (2006) have used the term *Homo consumericus* to refer to the Darwinian principles of evolution and consumer behavior. Lipovetsky has noted that modern times have brought about the rise of a third type of *Homo consumericus*, who is unpredictable and insatiable.

Homo Consumens is the man whose main goal is not primarily to own things, but to consume more and more, and thus to compensate for his inner vacuity, passivity, loneliness and anxiety...Homo Consumens is under the illusion of happiness, while unconsciously suffers from his boredom and passivity. The more power you have over machines, the more powerless it becomes as a human being; the more you consume, the more you become a slave to the ever increasing needs. (Fromm, 1965, p. 214)

Since then, most of the literature on symbolic consumption and consumerism has recreated this concept to deepen, if not openly criticize, a society that alienates the person, relegating it to a mere facet, often irresponsible and compulsive, and unconsciously, a buyer of increasingly sophisticated products and services. For example, Robert Bocoock (1995) states that consumption is a social, psychological, and cultural process that affects the way in which individuals establish and maintain an awareness of what they are or would be; Luis Enrique Alonso (2005) includes consuming as a form of material appropriation of the social surplus, understood as the production, circulation, and use of signs, circumscribing all practices of each

social position; Naomi Klein (2002), aligned with her “No Logo,” dared to raise a frontal attack on a logoized world; and Zygmunt Bauman (2007) points to how today’s world, with its globalization and the Web, cannot be understood without simultaneously considering, to a greater or lesser extent, consumers being consumers and consumer’s objects themselves: “individuals become simultaneously the promoters of commodities and the commodities that they promote” (p. 6). Even Adela Cortina (2002) raised the need to work toward a more conscious and critical consumption, without necessarily revolutionizing or destroying the system but reforming from within those aspects that do not work properly. Requena (2009) raised the possible existence of “consumers of nows,” the so-called transumers who would collect and accumulate “nows” in intense and prolonged fashion. Effectively, September 11, 2001, and its subsequent consequences, among which is a strong feeling of vulnerability (the collapse of the twin towers, representing the heart of capitalism, violated the consumer society, which could happen anywhere) caused us to believe that no future could be imagined, resulting in a feeling of *carpe diem*: Consume “nows,” because we do not know if there will be “afters.”

Thus, “we are all consumers,” as Kennedy said in his famous 1962 speech: “We are the largest market economic group, affecting and affected by almost every public and private economic decision.” In this developed society, it is true that we do not understand/cannot imagine our identity(ies) without that idea of being a buyers’ being. We are consumers, recognize ourselves as such, and cannot understand our society (relationships, institutions, symbols, and myths) without this essence. The concept of “mass man” (a term coined by Ortega in 1929) refers to the human being as characterized by a large increase in the consumption of goods and services of all kinds.

However, we know that there are not “consumers,” targeted as such and predictable in behavior throughout their existence, but consumption

habits, moments, and behaviors. The financial crisis, globalization, and social networks have changed the way people indulge in the satisfaction of their needs. Traditionally, consumers were labeled according to their behaviors and habits and classified in a particular segment according to sex, age, habitat, and life moment. Today, these classifications are geared more toward consumption moments in which each person behaves according to the circumstances: sometimes rational, sometimes emotional, sometimes price based, sometimes hedonistic. For example, you can be a manager by day, a parent on weekends, and a player at night. Thus, segmenting consumers is increasingly difficult, especially when they are now better informed, have become more demanding, and are sovereign in their decisions. It seems that Belk and Pollay (1985;889) were premonitory when they said, “We are building our identity in a way that had never before tasted”.

BACKGROUND

Homo Sapiens and Homo Consumens Ludens

Perhaps the first subclassification in this new taxonomy is to differentiate between rational and emotional consumers. The SmartShopper is logical and rational and tries to maximize a personal return on investment when buying food, household items, and even clothes, while the consumer is looking for emotions and experiences and seeking to enjoy every purchase. It is, however, that old distinction between “go shopping” and “do the shopping.”

It seems logical and even obvious to think that when a buyer chooses to purchase a good or service that he or she should always opt for that object that will provide greater value. The satisfaction of a need understood as that which fills the gap between a state that is presented as an ideal and a current state that keeps us unhappy is not only

the starting point of any action in marketing but also at the bottom of all advertising messages. Indeed, any slogan or advertising creation can be translated as “I’m the best solution to your problem.” Thus, *Homo sapiens* as consumers seek this solution among the functional characteristics of objects, while *Homo ludens* would be set on the components of what is called “extended product” (Kotler & Armstrong, 1999). Products compete not so much with their technical characteristics, more efficient after-sales service, or more useful or attractive packaging but for those experiences and feelings that the product causes the consumer: peace, pride, sympathy for the brand, and so on. According to some authors, in this world of mature capitalism where everybody has achieved an acceptable (even affluent) materialistic status, what is important is not to own but to feel (Davis, 2003). Physical needs have long ceased to be part of our priorities, because now what we seek is mental happiness. Thus, products are chosen according to how they can increase that spiritual happiness. Miller (2001) raised the idea that when acquiring certain objects we act simply as social primates trying to impress the opposite sex through the reactions of rejection or attraction based on what we wear or show to others. The best example of this experiential consumption is transmitted by the famous advertisement of a prestigious German car brand in which the driver’s hand is outside the vehicle’s window, playing with the wind in time to pleasant music, while the ad asks, “Do you like to drive?” Moreover, buying products with certain social characteristics, apart from the intrinsic value of the product, provide a pleasant feeling of contributing to a better world. People who do not have time or are not willing to provide another form of solidarity (volunteering, etc.) can contribute to solving the world’s problems from their everyday shopping baskets.

From Latin to English: Consumer and Prosumer

When Alvin Toffler coined the term *prosumer* in 1980, he was possibly thinking of those who produce for their own consumption. Thus, as in the early stages of the history of mankind, only a small part of the population could have the privilege of not hunting, growing, harvesting, or meeting their needs by their own means. In the postmodern era, there are people who choose to grow their own food or make their own clothes, which is likely due not so much to a need to cover basic requirements (a correct analysis of the effectiveness/efficiency of cultivating your own garden in purely economic terms would not hold) but in that need of *Homo ludens* alluded to in the preceding paragraph to experience something. Growing your own tomatoes, even a single plant in a pot on your terrace, provides a sense of pride and peace and cures stress. The do-it-yourself trend, sponsored by a financial crisis that has left us with less money to spend, has made us aware of the exaggerated and pernicious era of “throwaway” consumerism in our pursuit of shared leisure, family time, and booming new housing markets. “If Toffler is right with the rise of active prosumers’, marketing managers face a challenging future, if not frustrating” (Kotler, 1986, p. 510).

FUTURE RESEARCH DIRECTIONS: SOVEREIGN CONSUMERS

This brief taxonomy of consumers in a 3.0 era may conclude posing a need to empower and return sovereignty to the consumer. In economics, the consumer is always treated with respect and affection for it is the *raison d’être* of the market, the reason why that occurs and the object of desire of brands competing for your will, your faithfulness,

and your pocket. When looking at an economic dictionary for a definition of consumer sovereignty, such entries as “characteristic of a free market system where consumers orient production” and “Idea according to which consumers ultimately decide what should be produced (or not) by the act of choosing what will buy it (and what not)” often appear. Ultimately, it is the idea of consumer empowerment that becomes an undisputed market operator. The current development model based on economic growth and personal achievement towards individuals’ enrichment today is no longer a valid pattern. The idea that the world would be a better place if each would improve individually has been proved erroneous, because the achievement of somebody’s welfare (the less), according to this model, is at the expense of others (the more). The paradigm that happiness would come for possession of consumer goods and objects is taking us to a society of accumulation, which addresses us waste, pollution and injustice. The problem of being rich is the obligation of being happy every day.

Consumer, allegedly subject of rights and duties, can (although sometimes don’t want to) exercise them. In Europe theoretically, any citizen has the right to buy only what you want to actually buy. In practice this is not true. Consumer Rights are largely unknown and distant to the citizen and are written entirely with the individual consumer in mind. Protecting their safety, their health and their economic interests; promoting information and education of consumers and users with full freedom to choose (but don’t forget to choose), etc. Regarding duties is a simpler thing: the unique duty for a consumer seems to go shopping and pay. Rarely is referred the duty of every consumer to be informed about production conditions (social and environmental) of what he/she is buying, neither the responsibility to reduce consumption

However, this feature of a sovereign omnipotent that with its preferences guides the economy is not entirely true or tenable. In a competitive market and based on unbridled world consumption, the

trick is to convince consumers that they are free to choose whatever they want, whenever they want it. Like the absolute monarchs in the enlightened despotism of the 18th century who used their authority to introduce reforms in the political and social structures of their countries, we seem to be currently attending to an illustrated consumerism: Everything for the consumer but the consumer.

Precisely, this primacy of the individual consumer as market owner and master of this new concept of consumer sovereignty is counterpoised. If food sovereignty is the right of people to control their agricultural policies, to decide what to grow, to produce locally respecting the territory, and to control the natural resources (water, seeds, soil), then consumer sovereignty should be understood as the right of individuals to decide collectively and responsibly what, why, and where they want to consume. Consumer sovereignty, also known as “Consumocracy”, could be defined then as “a system by which consumers can exert moral or other authority on enterprises through a more enlightened selection of consumer products. It is therefore a voluntary regulation system within which corporate behavior is in part subordinated to consumer demands obeying both logics of individualism and voluntary solidarity”¹.

The market mechanism should serve as a form of political participation in which consumers move to rationality and utilitarianism as criteria fundamental to global transformation that puts people’s behaviors, the planet, and consumer relations in the center of the decision. Political consumerism is an expression used by Micheletti (2003, 2001), Andersen and Tobiasen, (2001) Barnett et al, (2005) Follesdal, (2006), Ballesteros (2007) that should be considered as the fundamentals of a new Theory of Revolutionary Consumption based in the well know French Revolution principles of Liberté, Egalité, Fraternité. As several authors have observed, for some individuals consumer behaviour is perceived as a means of making a public statement of personal values and beliefs, and/or as a means of influencing policy-making.

Authors have named this movement ethical consumerism (Shaw and Shiu, 2003; Shaw et al, 2006), consumer activism (Barnett et al, 2005; Smith, 2005) or political consumerism.

Micheletti's (2003) definition of political consumerism “actions by people who make choices among producers and products with the goal of changing objectionable institutional or market practices” (p. 2) assumes that political action can only occur through purchasing. This idea is reinforced when she explains the three types of political action. “[It] can take the form of exit, voice and loyalty, which equals boycotts, demands on producers, and smart shopping” (p. 15). Other authors have defined political consumerism in the same way, taking for granted that consumers can only express their political choices through purchasing (see Barnett et al, 2005; Follesdal, 2006; Shaw et al, 2006).

Consumer activism should therefore be considered as a new social movement (Hollenbeck and Zinkham, 2006, Kozinets and Handelman, 2004), and it can be done a distinction between two types of responsible consumers: reformers and revolutionaries, in the sense of the classifications of new social movements made by Held and McGrew (2002), Kiely (2000) and Starr, (2000). The difference between these two types is better understood by analyzing their targets and the form of power they are exercising. Let us focus first on the targets. The main difference between reformist consumers and revolutionary consumers lies in the targets they choose to attack. Reformists seek changes within the market, without contesting the current paradigm. Reformists choose the best performers and punish the worst ones: reformists boycott unethical brands and reinforce the best-in-class manufacturers. Therefore, their targets are specific examples of best (e.g. fair trade, organic food, best-in-class performer) and worst ways of production (e.g. unethical companies). However, for revolutionary consumers framing a decision as a choice between brand A and brand B is limiting the decision to the lesser of two evils. Revolutionary consumers, on the other hand, think first of

their needs, assess whether they are peremptory or not, and then decide whether they can satisfy them without engaging in an economic transaction. They believe that many purchasing decisions are not individual, rational or sovereign. On the contrary, individuals' purchasing decisions are heavily influenced by “contextual social forces” (e.g. corporate messages) and “structural forces” that make it necessary to increase or maintain consumption levels (Conca et al, 2001). Their targets are these nodes of power shaping consumption choices: they attack the structural roots of the social, economic, and political problems.

CONCLUSION: CONSUMER 3.0

The new consumer's conceptualization envisaged in this chapter is clearly aligned with the information science and technology society. The unlimited access to information that allows a more and better (empowered) consumer is crucial. The “prosumption” activity in social media is also a phenomenon broadly discussed in the literature as social networks in turn contribute to this need to create and produce as well as to consume.. A large number of Web 2.0 users are simultaneously content producers and consumers. YouTube channels, Facebook pages, Pinterest boards, Instagram photos.

From other perspective, social networking is clearly a consumer's activism tool. Worldwide consumers' unions are connected and develop campaigns through the internet. The firms' control by the consumers is permitted and enhanced through the exchange of knowledge that the information technologies allow. Apps for cellular phones which permits on-line comparison of prices and qualities while at the supermarket; web comparators that allows a smart-shopping behavior; the possibility to directly write to the company that market a product with an immediate response from the brand managers, etcetera, are good examples of how the new technologies contributes to this consumer empowerment.

KEY TERMS AND DEFINITIONS

Consumer Sovereignty: Characteristic of a free market system where consumers orient production.

Crowdsomers: Consumers who make use of the crowd platforms, both to take advantage of group purchasing and to participate in financing cultural projects or creating solidarity with minimum contributions (but operating in massive number).

Knowcosters: A movement initiated in Spain and posed by the need to consume as one thinks, knowing and being aware, in addition to the visible product costs (reflected in the retail price) of all indirect costs, which are not seen but paid by us, including planet welfare state cost.

Localsomers: Consumers rooted in their local consumption.

Presumers/Preconsumers: People involved in the process of creating products and services. By bringing an accelerated version to market, product forms often make companies decide to launch beta versions, which are improved and complemented with market use.

Trysumers: Consumers wanting to try new things.

Virgin Consumers: Consumers who increasingly meet with products that they do not know how to use, processes with which they are unfamiliar, and brands that they do not know and yet they are not afraid and decide to experiment, test, and comment on their experiences via social networks.

Wikisumers: Consumers or collaboratives exercise their right to consumption in nontraditional ways by sharing, exchanging, loaning, renting, and giving, all redefined through modern technology and communities.

Cyber and Network Security

Cyber Security Protection for Online Gaming Applications

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

By online gaming applications, we mean both distributed applications that enable large number of users to play multiplayer games and those that enable people to gamble online because both types of applications could have huge financial stakes and the security and dependability challenges for both are rather similar. On the one hand, such systems must ensure continuous high availability so that users around the globe could play the games 24 by 7. This requires that the game servers be replicated to provide non-stop services. On the other hand, state-machine replication requires that the replicas be deterministic or rendered deterministic. This requirement does not work well with gaming applications because random numbers are essential to their operation. For example, in a card game, the random numbers are used to shuffle the cards. If the random numbers used are not robust, the hands in the card game may become predictable, which could damage the integrity of the game and may lead to financial losses to the game provider and/or honest game players. The nature of this type of applications poses a particular challenge to ensure cyber security because it is difficult to ensure high availability while preserving the integrity of the operation of these applications (Arkin et al., 1999; Viega & McGraw, 2002; Young & Yung, 2004; Zhao, 2007; Zhao, 2008; Zhang et al., 2011).

Byzantine fault tolerance (Castro & Liskov, 2002) is a well-known technique to achieve cyber security (Zhao, 2014). The technique aims to tolerate various malicious attacks to online systems by employing state machine replication (Schneider,

1990). However, as we mentioned earlier, Byzantine fault tolerance cannot be used as it is because it is not equipped with built-in solution to resolve the conflict of replication determinism requirement and the intrinsic randomness of the server operation. In this article, we elaborate how we address this dilemma using an online poker game application as a running example. In this application, a pseudo-random number generator (PRNG) is used to generate the pseudo-random numbers for shuffling the cards. We present two alternative strategies to cope with the intrinsic application nondeterminism. One depends on a Byzantine consensus algorithm and the other depends on a threshold signature scheme. Furthermore, we thoroughly discuss the strength and weaknesses of these two schemes.

BACKGROUND

In this section, we provide a brief introduction of PRNG, the entropy concept, and the methods to collect and enhance entropy.

A PRNG is a computer algorithm used to produce a sequence of pseudo-random numbers. It must be initialized by a seed number and can be reseeded prior to each run. The numbers produced by a PRNG are not truly random because computer programs are in fact deterministic machines. Given the same seed, a PRNG will generate the same sequence of numbers. Consequently, if an adversary knows the seed to a PRNG, then he/she can generate and predict the entire stream of random numbers (Young & Yung, 2004). Therefore, to make the random numbers unpredictable,

it is important that the seeds to the PRNG cannot be guessed or estimated. Ideally, a highly random number that is unpredictable and infeasible to be computed is required to seed the PRNG in order to produce a sequence of random numbers.

The activity of collecting truly random numbers is referred to as “collecting entropy” by cryptographers (Young & Yung, 2004). Entropy is a measure of the degree of randomness in a piece of data. As an example, consider using the outcome of coin flipping as 1 bit of entropy. If the coin-toss is perfectly fair, then the bit should have an equal chance of being a 0 or a 1. In such a case, we have a perfect 1 bit of entropy. If the coin-toss is slightly biased toward either head or tail, then we have something less than 1 bit of entropy. Entropy is what we really want when we talk about generating numbers that cannot be guessed. In general, it is often difficult to figure out how much entropy we have, and it is usually difficult to generate a lot of it in a short amount of time.

It is a common practice to seed a PRNG with the current timestamp. Unfortunately, this is not a sound approach to preserve the integrity of the system, as described by Arkin et al (1999) in the context of how a Texas Hold'em Poker online game can be attacked. They show that with the knowledge of the first few cards, they can estimate the seed to the PRNG and subsequently predict all the remaining cards.

TECHNIQUES FOR ENHANCING THE TRUSTWORTHINESS

In this section, we describe two possible strategies for enhancing the trustworthiness of online gaming applications. One depends on a Byzantine consensus algorithm and the other depends on a threshold signature algorithm. Both algorithms ensure that all replicas adopt the same value to seed their PRNGs, while each replica is taking entropy from its respective entropy source.

Byzantine Fault Tolerance

A Byzantine fault (Lamport, Shostak, & Pease, 1982) is a fault that might bring a service down, or compromise the integrity of a service. A Byzantine faulty replica may use all kinds of methods to disrupt the normal operation of a system. In particular, it might propagate conflicting information to other replicas. To tolerate f Byzantine faulty replicas in an asynchronous environment, we need to have at least $3f+1$ number of replicas (Castro & Liskov, 2002). An asynchronous environment is one that has no bound on processing times, communication delays, and clock skews. Internet applications are often modeled as asynchronous systems. Usually, one replica is designated as the primary and the remaining ones as backups.

Any robust Byzantine fault tolerance (BFT) algorithm can be modified to cope with the use of random numbers. In the following, we describe a solution based on the well-known Practical BFT (PBFT in short) algorithm developed by Castro and Liskov (2002). The PBFT algorithm has three communication phases in normal operation. During the first phase, the pre-prepare phase, upon receiving a request from the client, the primary assigns a sequence number and the current view number to the message and multicasts a Pre-Prepare message to all backups. In the second phase, referred to as the prepare phase, a backup broadcasts a Prepare message to the rest of replicas after it accepts the Pre-Prepare message. Each non-faulty replica enters into the commit phase, i.e., the third phase, only if it receives $2f$ Prepare messages (from other replicas) that have the same view number and sequence number as the Pre-Prepare message, then it broadcasts the Commit message to all replicas including the primary. A replica commits the corresponding request after it receives $2f$ matching commit messages from other replicas. To prevent a faulty primary from intentionally delaying a message, the client starts a timer after it sends out a request and waits for $f+1$ consistent responses from different replicas. Due to the assumption that at most f replicas can

be faulty, at least one response must have come from a non-faulty replica. If the timer expires, the client broadcasts its request to all replicas. Each backup replica also maintains a timer for similar purposes. On expiration of their timers, the backups initiate a view change and a new primary is selected. In the PBFT algorithm, digital signature or an authenticator is employed to ensure the integrity of the messages exchanged.

The above PBFT algorithm is modified in the following way to cope with the replica nondeterminism caused by the use of random numbers. The modified algorithm also consists of three phases, as shown in Figure 1. In the beginning of the first phase, the primary invokes ENTROPY-EXTRACTION operation to extract its entropy and append the entropy to the Pre-Prepare message. It then multicasts the Pre-Prepare message to the backups. Each replica records the primary's entropy from the Pre-Prepare message in its log and then invokes the ENTROPY-EXTRACTION operation to obtain its own share of entropy as well.

Each backup then multicasts a Pre-Prepare-Update message, including its share of entropy extracted. When the primary collects $2f$ Pre-Prepare-Update messages from the backups, it constructs a Pre-Prepare-Update message, including the digest of the $2f+1$ entropy shares ($2f$ received, plus its own), together with the corresponding contributor's identity, and multicasts the message.

Upon receiving the Pre-Prepare-Update message from the primary, each replica invokes the ENTROPY-COMBINATION operation to combine the entropy from the $2f+1$ shares. The outcome of the ENTROPY-COMBINATION operation ensures a highly random number, due to the contributions from the non-faulty replicas. The combined number is provable secure and will be used to seed the PRNG if the BFT algorithm terminates.

The second and third phases are similar to the corresponding phases of the PBFT algorithm, except each replica will append the digest of the entropy set determined in the first phase to the

Figure 1. The adapted BFT algorithm to handle entropy extraction and combination

Prepare and Commit messages. These two phases are necessary to ensure all nonfaulty replicas to agree on the same message total ordering and the entropy value despite the presence of Byzantine faulty replicas.

We now highlight the details of the ENTROPY-EXTRACTION and the ENTROPY-COMBINATION operations.

Entropy-Extraction

The ENTROPY-EXTRACTION operation is based on software-based entropy collection. There are a number of techniques that can be used to extract the entropy, most of which are based on the timing of internal activities in a computer (Young & Yung, 2004). A well-known technique is called TrueRand, developed by Don Mitchell and Matt Blaze. The idea behind TrueRand is to gather the underlying randomness from idle CPUs by measuring the drift between system clock and the generation of interrupts on the processor. Other frequently used techniques include recording network traffic as it comes into the server, timing how long it takes to seek the disk, and capturing kernel state information that changes often.

Entropy-Combination

The ENTROPY-COMBINATION operation combines the $2f+1$ entropies the replica collected using the exclusive-or (XOR) operator (Young & Yung, 2004). This operation has several benefits.

First, it combines a number of weak sources of entropy to form an effective strong entropy source. Consider two entropy sources from coin flipping, and the case which source 1 results in head and source 2 results in tail, or source 1 results in tail and source 2 results in head, and the probability for source 1 to result in head is $10/16$ and that for source 2 is $12/16$ (i.e., both are biased). If we combine these two sources, the probability of getting a head is $7/16$. This shows that the coin flipping resulting from XOR-ing the bits from the two sources is the same or better than the best

flip in either of the two sources. Furthermore, the more sources we use, the higher entropy we get.

Second, the ENTROPY-COMBINATION operation eliminates any negative impact from malicious replicas. Among the $2f+1$ entropy shares collected, there can be up to f of them coming from faulty replicas. The XOR operation guarantees that if at least one share coming from a good entropy source, the combined entropy is at least as good as that entropy share. This requirement is met because there are at least $f+1$ shares contributed by non-faulty replicas. Any low-entropy or predictable shares generated by faulty replicas are virtually ignored.

Third, the ENTROPY-COMBINATION operation results in a single high entropy share used by all non-faulty replicas, which ensures the consistency of the replicas when they are involved with intrinsically nondeterministic operations.

Threshold Signature

The other strategy to ensure consistent Byzantine fault tolerance replication for nondeterministic operations is to employ threshold cryptography (Deswarte, Blain, & Fabre, 1991; Desmedt & Frankel, 1990). Threshold cryptography is a good way to distribute trust among a group of players to protect either information or computation (Zhou, Schneider, & Renesse, 2002).

A well-known secret sharing scheme (Shamir, 1979) is the (k, n) threshold digital signature scheme. In the (k, n) secret sharing scheme, a secret is divided into n sets and distributed to the same number of players. The secret can be reconstructed if k out of n number of players could combine their shares. However, fewer than k players cannot collude to forge the secret. The (k, n) threshold digital signature scheme allows a set of servers to collectively generate a digital signature in a way similar to reconstructing a secret using the (k, n) secret sharing scheme.

In the (k, n) threshold digital signature scheme, a private key is divided into n shares, each owned by a player. To produce a valid threshold digital

signature, at least k players must pool their shares together (i.e., fewer than k players would not be able to generate a valid threshold digital signature). Each player uses its private key share to generate a partial signature on a message and these partial signatures can be combined into a threshold signature on the message. The threshold signature can be verified using the public key corresponding to the divided private key.

The RSA Shoup scheme (Shoup, 2000) is one of the practical threshold digital schemes. In this scheme, a dealer generates a key pair and divides the private key into n shares at first. Each key share has a key verifier. Then the dealer distributes the message to be signed and the key shares to n players. Each player uses its key share to generate a partial signature on the message. Furthermore, each player sends the signed message with the verifier to a trusted server, which verifies the signature shares and combines the partial signatures into a threshold signature verifiable by the public key.

In the following, we show how to integrate the threshold digital signature scheme with Byzantine fault tolerance for online gaming applications. The adapted PBFT algorithm consists of three phases (under normal operation) for Byzantine agreement and an additional phase run at the beginning for key shares distribution. The Byzantine agreement algorithm works similar to the PBFT algorithm except the third phase, where each replica generates a partial signature (using its key share) to sign the client's message and piggybacks the partial signature to the Commit message. Each replica combines the partial signatures into a threshold signature. The signature is then mapped into a number to seed the PRNG.

Despite the elegance of the threshold signature, the algorithm, however, might not be practical in the Internet environment. First of all, it depends on a trusted dealer at the beginning to generate a key pair, divide the private key into several key shares and it must also be responsible for distributing the key shares to all replicas. If the dealer is compromised, the entire system would become vulnerable to adversaries. Furthermore,

the threshold signature is computationally expensive, especially when generating the threshold signature. For example, for a 1024-bit threshold signature it usually takes 73.9ms on a PC equipped with a single 1.0GHz Pentium III CPU and 1.5 GB RAM (Rhea et al., 2003). Furthermore, the validity on the use of the threshold signature as the seed to the PRNG remains to be proved secure.

FUTURE TRENDS

Not only for online gaming applications, PRNGs are widely used in nearly every field in computer and networking area. In particular, for cryptography, the access to truly random numbers is extremely important. Even though there is moderate success in implementing PRNG, it remains to be vulnerable under cryptanalytic attacks and the attacks against its internal state. Furthermore, it is easy to see that even if the PRNG is robust against many potential threats, once the seed is discovered the numbers generated by the PRNG are no longer unpredictable. In light of this observation, more efforts should be engaged in how to gather and evaluate entropy in a secure and dependable manner. The research described in this article can be regarded as the first step towards this direction.

There are many open issues to be resolved before we can confidently apply these techniques in practice. The most interesting research issue is how to maintain replica consistency. Common Byzantine fault tolerance techniques require deterministic execution of replicas despite the fact that all practical applications contain some degree of nondeterminism (Zhao, 2007), for example, clock values, CPU speed, multithreading, etc. Note that these types of nondeterminism are not considered as good entropy sources accordingly to the cryptography standard, but the presence of these types of nondeterminisms nevertheless poses a big threat to maintaining replica consistency. We recently proposed a Byzantine fault tolerance framework that is able to handle various

nondeterministic applications in a systematic and efficient manner (Zhang et al., 2011).

So far we have focused on addressing the issues for the client-server based online gaming applications. Peer-to-peer (P2P) based online games have become popular in recent years. The P2P design brings additional challenges to enhancing trustworthiness of such applications because each client maintains substantial private state. There are new attacks that may be launched from clients to the systems. Various schemes have been designed to enforce the integrity of such applications (Jha, 2007; Wierzbicki, 2006).

Finally, we only addressed the high availability and the associated integrity issues for online gaming applications. Additional research is needed to address other aspects of risks faced by such applications. For example, a player could cheat by changing the rendering routines so that he/she could see scenes that are not allowed, thereby gaining an unfair advantage over honest players. These types of threats cannot be addressed by resorting to replication.

CONCLUSION

In this article, we pointed out the threats to online gaming applications and presented two strategies that can be used to build secure and dependable online gaming applications. These strategies not only seek the solution for gathering entropy to seed the PRNG used in such applications, but also intend to eliminate malicious intrusions to protect the seed and to maintain replica consistency. By applying these techniques, the online gaming applications can ensure its service integrity (both the service providers and the innocent players are protected) and guarantee high availability despite the presence of Byzantine faults. Finally, we outlined some open research issues in this field.

KEY TERMS AND DEFINITIONS

Byzantine Fault Tolerance: A replication-based technique used to ensure high availability of an application subject to Byzantine fault.

Byzantine Fault: It is used to model arbitrary fault. A Byzantine faulty process might send conflicting information to other processes to prevent them from reaching an agreement.

Dependable System: A dependable system is one that is trustworthy to its users. It requires that the system to be highly available (to legitimate users) while ensuring high degree of service integrity.

Digital Signature: A digital signature aims to serve as the same purposes as a real-world signature. A sound digital signature ensures that the sender of the digital signature can be authenticated, the sender cannot later repudiate that she has sent the signed message, and a receiver cannot forge a digital signature (without being detected).

Entropy Combination: The operation that combines a number of entropy shares into one. The combination is usually achieved by using the

exclusive-or (XOR) operator. Entropy combination is an effective defense against adversaries that substitute a random value by a predictable one. The combined entropy is often of higher quality than each individual share.

Entropy Extraction: The operation that extracts entropy from a random variable (referred to as the entropy source). Entropy can be extracted using both software and hardware based methods.

Entropy: A metric used to evaluate and describe the amount of randomness associated with a random variable.

Pseudorandom Number Generator (PRNG): A PRNG is a computer algorithm used to produce a sequence of pseudo-random numbers. It must be initialized by a seed number and can be re-seeded prior to each run. The numbers produced by a PRNG are not truly random. Given the same seed, a PRNG will generate the same sequence of numbers.

Threshold Digital Signature: In the (k, n) threshold digital signature scheme, a private key is divided into n shares, each owned by a player. A valid threshold digital signature can be produced if k players combine their shares. However, no valid signature can be generated by fewer than k players. Each player uses its private key share to generate a partial signature on a message and these partial signatures can be combined into a threshold signature on the message. The threshold signature can be verified using the public key corresponding to the divided private key.

Piracy and Intellectual Property Theft in the Internet Era

INTRODUCTION

Internet has quickly become an essential part of contemporary society across country borders for its capacity to offer a wide array of functions, ranging from information distribution, communications, financial and business management, to entertainments. Also, the Internet has evidenced itself as a unique medium with the fastest speed of diffusion in human history. With hundreds of thousand miles of optical fiber that connect servers and mega-storing devices together globally, several terabytes of digital information, as huge as those stored in the U.S. Congress Library, can be easily transferred from one end of the world to the other within minutes (Britz, 2013). In conjunction with widely available Wi-Fi and telecommunication (e.g., 3G, 4G, LTE) in many areas of the world, it is never this easy for an average user to transmit valuable information in digital format via mobile devices.

The information technology advances with incremental innovation, but business is the instrument that facilitates the widespread of the technology. The mechanism of business determines when to release certain technology, and the nature of business makes it user friendly for the purpose of obtaining a larger market share and a higher level of profit (Felson and Clarke, 1997). While legitimate opportunities are created in the process, some offenders may take advantage. Like many innovations that have a tendency to crime (Merton, 1968), the growing capacity of Internet probably is too good to be true, as it has created

new forms of intellectual property (IP). Before further discussing IP and elaborating the victimization of piracy, background of some theoretical frameworks of crime is necessary.

BACKGROUND

Basic Elements of Crime and Socio-Technical Gap

In their theory of crime, Cohen and Felson (1979) point out three elements of a crime incident: a suitable target, a motivated offender, and the absence of capable guardians. A suitable target is something valuable to potential offenders, and the target must be easy enough to be removed. Although crime rate is the highest among young males, motivated offenders can be anybody in the population, if an adequate opportunity is present. The guardians against crime do not necessarily refer to law enforcement. Instead, the owner of the targeted property, friends and neighbors of the property owners serve better roles of capable guardians that discourage potential offenders. In the scenario of burglary, potential perpetrators probably would less likely to choose houses that the owners are present or their friends/neighbors pay attention to. In the business settings, for another example, an office suite's receptionists who watch people entering the office can serve as the role of guardian. In sum, for a crime to occur, the above three elements have to emerge.

There is little doubt that industry has incentives to make their products lighter, more portable, more convenient, and more added functions and values, but this tendency naturally leads to some unwanted consequences of the products, such as suitable targets to theft. However, the social system (e.g., laws, justice agencies) usually simply reacts to the consequences of technological advancements pushed by industry and business. That is, technology proactively runs at the front, and the social system passively chases behind and (hopefully) fixes problems and challenges. In the era of Internet, the discrepancy between fast-growing Internet and information technology and the slow-reacting social system in the virtual space has created a cybergap in which crimes emerge (Huang and Wang, 2009). Explicitly, many more new digital IP are valuable targets with little to no meaningful guardians that trigger motivation of potential offenders in the cyberspace. The following section provides a description of IP theft and piracy. The discussion of IP and piracy in the present article is focused within the arena of those using digital technology, with an intention to compare and contrast several major incidents.

IP, IP Theft, and Piracy

The discussion of IP traditionally revolves copyrights, patents, trademarks, and trade secrets. Piracy has been generally defined as “the unauthorized use or reproduction of another’s work,” and it encompasses any individual or corporation that utilizes intellectual property in a digital form without the authorization of the originator (Business Software Alliance, n.d.; Filby, 2007). The nature of such behaviors is perceived as illegitimate, with some noticeable variation across different levels of civilization and cultures. For example, in some Asian societies with long histories, scholarly works are traditionally viewed as public goods contributing to the advancement of the entire society, and the scholars are informally “rewarded” with socially-recognized reputations and their social status. On the other hand, in the

United States and many European countries, where the right of tangible or intangible personal property are better defined and protected by laws, such kind of theft has been criminalized. Generally speaking, intellectual properties are well respected, formally and informally, in civilized societies.

Properties can be generally divided into tangible and intangible items, and the age-old theft usually involves tangible goods that perpetrators have to physically move away and turn into financial gains. IP theft is different from stealing of physical property in many ways: IP theft implies depriving people of their ideas, inventions, or creative expressions, and thereby this type of asset is intangible. Nevertheless, it is not saying that there is no overlapping between tangible and intangible properties, as IP also requires some kind of medium to load on, to store, or to distribute. For instance, the physical piracy of music – the production and/or distribution of illegally made copies of sound recordings without the consent of the rights proprietor – needs cassettes, discs, USB, hard drives, or other storing media. Within the past two decades, the significant improvement of personal computing devices equipped with large storage capacity inflamed the popularity of digital IP. In addition, in conjunction with growing Internet users, the expanding capacity of broadband and wireless technology increases the movement of digitalization. Collectively, the advancement of information technology has dramatically increased the amount of IP in digital format.

Based on the contents, there are two broad groups of highlighted IP: entertainment (music¹, movies, games, TV programming, etc.) and instrumental software. This typology is adopted for its exhaustive categories that ease the discussion, although ‘Internet piracy’ and ‘digital piracy’ are the terms used more often in varied news media and public reports. Internet piracy is a somehow broadly used term which generally means that the Internet is employed to distribute unauthorized creative content amongst users², and this term is used to generalize any use of creative content on the Internet that infringe on copyright laws

(Higgins, 2011). It had been a common myth to some that customers who purchase a legal copy of a music CD or USB believe that they own the music because they bought it in the format of optical disc or portable storage. In fact, the ownership of the recorded music, as a form of IP protected by the copyright laws, belongs to the writers. Consequently, if the purchasers massively multiply the disc/USB or upload the content to computers and share with others via the Internet, they would be committing so-called 'Internet piracy.' In a similar vein, piracy offenders may use the Internet for advertising, offering, acquiring, or distributing of other copyright protected contents.

Naturally, IP theft and piracy are business-threatening issues to the corporations of the ownership, and they can be problems to individuals as well. Intuitively, the pirated copies, which may appear to be legitimate ones, hurt the profit of the producing industry. Counterfeits sound recordings are produced without the required permission of the proprietor and then packaged to bear a resemblance to the original. Another noticeable type of piracy, bootlegs, consist of recording live or broadcast concerts without the consent of the proprietor that are replicated and re-sold. Similar violation may include other forms of performance and artworks. These actions are taken to mislead customers into believing that they are buying an original (and legal) version and supporting the creations.

The other substantial IP subject to today's piracy is instrumental software. Software piracy is commissioned by unlawfully multiplying or distributing of copyrighted software with the intention to gain financially. Legally purchased software (only) grants buyers the licenses of usage. The consensus, as it is reflected in the laws in many developed countries, is that buyers pay for user licenses, not the ownership of the IP of software. Based on the purpose and volume of duplication, two categories of software piracy are recognized: end user piracy and reseller piracy. End user piracy is the installation of the software onto computers or terminals exceeds the user license

allows. Reseller piracy occurs when an individual or an organization consciously produces multiple copies of the software for the purpose of selling for profits. Sometimes, pirate copies even come with counterfeit certificates with an obvious intent to deceive purchasers. In sum, copying, downloading, installing, sharing, or selling multiple copies of copyrighted software are behaviors subject to software piracy.

Corporations have adopted a good number of strategies to fight against software piracy. The most straight-forward method is to establish a call-free reporting hotline by the corporations. The operating system giant Microsoft, for example, utilized its anti-piracy hotline to collect information and sued 8 Toronto-area computer resellers suspected of unlawfully dispensing unlicensed software. The lawsuit was the single largest piracy sweep operation in a North American city of the time (National Post, 1999). A related strategy, similar to criminal case reporting system or campaign (e.g., "see something, say something"), is collaboration among stakeholders and offer meaningful incentives to encourage reporting. Business Software Alliance (BSA) promoted a program named "know it, report it, reward it" that provides qualified individuals who report software piracy a cash reward of up to \$1 million. This program led to a lawsuit that BSA filed against a Nevada based engineering company that duplicated and distributed unauthorized copies of Autodesk software used for drafting (PR Newswire, 2009). Another developed approach is working with direct-related industries or holding them legally accountable, such as Internet platform providers. In 2008, the Software and Information Industry Association (SIIA) filed nine separate lawsuits on behalf of members of Adobe Systems and Symantec alleging that the defendants deliberately sold illicit copies of software on eBay (The Daily Record of Baltimore, MD., 2008). This largest round of lawsuits, since eBay initiated its auction website anti-piracy program, signaled the seriousness of the issue and also sent out a clear message to similar industries. Still another approach is called digital

rights management (DRM) that places control over digital products. The methods of managing the digital products can be as simple as entering serial numbers to activate installed software, and the methods can be as sophisticated as requiring authentication with an online server and/or with a smart-card (Kumari, Khan, & Li, 2016). This approach has been adopted to ensure authorized access, distribution, and consumption of the products/services by software and entertainment companies. The implications of this approach can cover the entire lifecycle of the digital products.

Amplified by the global economy, the matter of IP theft and piracy can be much more complicated and worse when the majority of IP thefts initiated outside of the property owner's country territory where the right of IP are usually better protected by laws. Traditionally, stealing of ideas emerged in the developing countries where the criminal and civil laws are permissive and the enforcement of law is more likely to be compromised for economic reasons. However, Sweden has ironically been a piracy haven because of the well-known file-sharing website Pirate Bay is hosted within its territory. Although the Swedish court system convicted four major players of the website and punished them with prison sentences and a substantial amount of fines in 2009, the website is astoundingly running (Pfanner, 2009)³. Another extreme example is the entire counterfeit Apple store, in which the staffs even believe that they are Apple employees, found in Kunming, China (BBC, 2011), and such kind of "fake" Apple store did not seem to exist solely (Chang, 2015). It appears that some well-off Chinese appreciate real Apple products by paying double amount of the money, but they do not seem to care the sources of IP products. At the same time, surveys show that the overall rate of IP infringement in mainland China is close to the global average (Broadhurst, Bouhours, & Bouhours, 2013).

Proactive approaches to combating piracy have been spread both domestically and internationally. For example, in 2006, the United States government created an organization called Strategy

Targeting Organized Piracy (STOP) in an effort to deal with piracy. Following suit was the European Union that has created a different strategy based off of the STOP ideology. The European Union began working with some developing countries through effective implementation and enforcement of existing laws of IP. This proactive approach by both the United States and the European Union has in turn influenced the Nigerian government, for example, to take similar actions. The Nigerian government worked in partnership with the private sector and other stakeholders to set up the Strategic Action Against Piracy (STRAP), and the Nigerian Copyright Commission (NCC) worked with Microsoft to combat piracy (Africa News, 2006).

VICTIMIZATION OF PIRACY AND IP THEFT AND PROTECTIVE ACTIONS

The victimization of piracy and IP theft usually involves multiple parties in different context. The advancing information technology makes it easy for pirating websites to sell illegally duplicated IP, or even portray themselves as a legitimate business to deceive inexperienced online consumers⁴. In another scenario, many people who acquire pirated software over the Internet never actually receive the software or entertainment items they paid for. In that sense, those who consciously purchase pirated IP online potentially play dual roles: law violators and victims.

There used to be a clear-cut distinction between the victim(s) and the offender(s) when a criminal act takes place. We have little to no doubt that a street thief who snatches a purse is the obvious criminal offender, and the victim is the individual whose purse was stolen. As this series of behavior occurs in the physical world, it could be witnessed by others or video recorded by devices that leave evidence for criminal investigations. However, the Internet has changed the rule, and thereby somehow changes the distinction between victims and offenders. With the advancement of information

technologies, the physicality of traditional crimes has become intertwined with the creation of new types of criminal acts in the cyberspace, which are much less visible. Internet also substantially lowers the threshold of committing crimes, especially true in the violation of IP – clicking the mouse or touching on the screen and downloading a pirated copy of software, film or music from a remote server (wherever it is physically located in the world) can be a violation of criminal codes! Furthermore, the sense of borderless of many cybercrimes complicates the issue, as multiple countries, with a general disagreement about the seriousness of IP violations, are typically involved (Altbach, 1988). Collectively, it has become more challenging to define a victim in an intellectual theft incident. This has also created burdens on policy makers and police when defining and enforcing new criminal and civil statutes intended to protect truly innocent victims.

In the short history of digital piracy, the creation of Napster and its impact on music industry is one of the important milestones. In 1999, Shawn Fanning, a college student at the University of Boston, created an online music peer-to-peer file sharing service called Napster. This ground-shaking service allowed some music enthusiasts around the world to share music with each other without purchasing music CDs or tapes from physical stores. From many aspects, Napster could be a successful business, as it rapidly became the largest platform of music sharing of the time. Rather, Napster has often been blamed from the economic perspective – its existence leads to a major revenue loss of recording industry. Largely because of the erosion of industry's profit, the Recording Industry Association of America (RIAA) sued Napster on behalf of the major record labels and proprietors (musicians) that are the victims of music piracy (Richtel, 2001). RIAA won the law suit, however, the winning lawsuit that shutdown Napster did not lead to the intended consequences – regain billions of dollars in potential revenue. In contrast, the result in Napster's disappearance created a number of unregulated peer-to-peer file sharing

networks such as BearShare, Grokster, Gnutella, KaZaa, Morpheus, Pirate Bay, and others (Dodge, 2005). Even in a report, IFPI (2010) claims that the revenues from recorded music reduced by 50% in a decade after the creation of Napster. In a sense, the RIAA probably ironically retain the financial damages to its party by shutting down Napster instead of working with this emerged online platform, which once had 38 million users, to rectify their strategic flaws of business. The law case symbolizes the significance of copyrighted content protection, but the music industry is still somehow suffering from this lawsuit. The advancement of related information technology has made it difficult for corporations to protect themselves from being victimized, if the fundamental changes that can be made by new technologies are not carefully appraised. It is hard to deny that “as long as Philips makes and sells CD burners, and as long as Sony makes and sells MiniDisc players/recorders, they're directly profiting from the very technology that they claim is hurting them” (Rodman & Vanderdonckt, 2006: 253). In other words, the increase of digital piracy of music and the decline of music industry revenues are largely the consequences of information technology advancement.

Piracy of music has existed for decades, but digital piracy of music significantly hit the industry because of its slower, if not unwise, response to the technologies, in addition to passive response from the social system (Huang & Wang, 2009). An interesting fact is that the successful business model of selling music online was accomplished by a computer company, not the music industry – Apple introduced iTunes online music store after Napster lawsuit, and it remained its leading place in the market when this manuscript was prepared in 2016.

In addition to corporations being impacted by the emerged cyber-platforms, individual users are subjects to corporations' legal actions. In 2003, the music recording industry sued over 200 Americans for sharing songs on peer-to-peer file sharing networks, and the message cannot be

clearer when a minor living under poverty was on the list. Moreover, the recording industry has filed, settled, or threatened legal actions against at least thirty thousand individuals in order to protect its potential profits. It probably is socially justified to consider these individual offenders in that they illegally shared intellectual property, regardless the media that are used. However, the proportionality of penalties (e.g., charges and retributions that these individuals have to pay) and damages might be debatable. To some, this case makes sued individuals become scapegoat when the balance and rules are greatly impacted by the introduced new applied technology. For instance, Jammie Thomas of Brainerd, MN was accused of unlawfully sharing over 1,500 songs, and the RIAA lawsuit sought damages under a federal law that allowed a fine of \$750 to \$30,000 for each copyright violation, which totaled a judgment of over \$1.2 million (Freed, 2007). To others, “it’s stupid (and reckless) to antagonize one of your principal sources of long-term income by publicly attacking them as criminals” (Rodman & Vanderdonckt, 2006: 259).

Similarly, the widespread of BitTorrent and illegal download of movie contents had significantly impacted revenues of film makers. Another important milestone of combating piracy is focusing on sites that offer free massive online storage space, which were misused by some to store and share contents of large files, such as movies. In a recent study that assesses the economic impacts of supply-side intervention of illegal downloading indicates that the shutdown of Megaupload⁵ chronologically leads to a significant increase in digital sales and rentals. Countries with higher pre-shutdown usage of Megaupload experience larger increase of digital sales than their counterparts with lower pre-shutdown usage do (Danaher & Smith, 2013).

IP theft and piracy will undoubtedly continue to occur, but the approaches of solutions can be different. In the case of film and music piracy, it will be up to stakeholders, including policy

makers, legal experts, and the industry to come out a balanced approach. More efforts should be taken placed in innovative ways to better educate consumers about sharing movies and music and to reduce costly legal actions. A more recent case of a Vietnam-based social media website “Zing,” which includes an infringing deeplinking music portal, shows that collaborations, instead of lawsuits, may have been identified as a win-win solution between right holders and online platforms (Executive Office of the President of the United States, 2012).

FUTURE RESEARCH DIRECTIONS

From the preceding sections, the trend of working with continuously-advancing information technology and online platforms instead of fighting against it appears to be a more effective approach in IP protection with more beneficial results to stakeholders. Although the Internet is borderless, the undeniable “territory” in cyberspace is largely structured by users and administrations’ nationality, culture, ideology, and language, which is somehow related to their geographical locations. Future research can systematically compare cases in the area of IP protection strategies and evaluate their outcomes across different geographical regions and industries. Instead of narrowing down to the benefits of certain stakeholders like music industry, the outcomes should include social and economic indicators that capture the impacts on the development of legal system and competitive advantage of the economy. Future research probably should investigate the impacts of cultures, including pop cultures, on how people perceive and support IP rights. Given some contradicting phenomenon between international survey findings and news reports, using dimensions like the socioeconomic development, level of civilization, and law protections seem to overly simplify global citizens by their nationality.

CONCLUSION

The main challenge of piracy and IP violations that today's societies face is the discrepancy between the fast-pace information technology, which is believed by some to lead advancement of human societies, and the slow reactions of laws, which is supposed to guide and protect citizens. The rapid progression of technology, combined with weak laws, has allowed criminals to exploit the international community and run illegal "business" of piracy. As a result, the entertainment and software industries, in particular, have been victimized of extensive pirating schemes, which have caused substantial revenue and job loss worldwide. Information technology has greatly expanded the avenues that copyright-protected works can be duplicated and distributed, while lowering the costs. After the mass investment of optical fiber in late 1990s, the Internet has facilitated the transfer of vast amounts of information among large numbers of people at little cost to law violators. But, the cost of piracy, ranging from financial, economic, safety, to health, is tremendous to the IP owners and the entire society, as the pirates require no investment in research, development, and warranties, and consumers are risked by failing counterfeiting parts and products.

The uniqueness of Internet's fastest diffusion, along with the reactive nature of social system, has created a good number of challenging social issues in the socio-technical gap. From a criminological perspective like routine activities, this information super highway does provide very fast transportation of attractive targets with some to not-meaningful guardians in the cyberspace to motivated (and somewhat skilled) offenders. The Internet and related technology might have also blurred the clear line of ownership of productive assets, as well as the products and services originate from them. These clear lines are central to the foundation of capitalism; the social system cannot continue to function without a set of understandable rules that define ownership of the properties and legitimate business models (Thurow, 2000).

Rather than making progress, the system would fall apart starting from the erosion of the incentive structure that encourages the continuity of research and development, which leads to further loss of trust in business and confidence in the economy (van Dijk and Terlouw, 1996). Indeed, the Internet probably has brought another wave of significant challenges to the issues of intellectual property and piracy, since Xerox introduced its first commercial photocopy machine in 1959.

The advancement of information technology has also intentionally increased digitalized IP and "migrate" those in earlier generation formats to the cyberspace. The Internet search giant Google, for example, has implemented many ambitious projects to massively digitalize social artifacts. There is no doubt that information is so affordable to so many people in the human history because of the Internet, and Google, so far, has been the leading private provider that effectively organizes and prioritizes the online contents to the majority users of the developed countries. While some may argue against Google's project of "displaying" instead of "copying" the IP in the cyberspace, another wave of concern of IP and piracy may involve the conflicts between the profit-making nature of business and the belief of public-belonging of human heritage (Vaidhyanathan, 2011).

KEY TERMS AND DEFINITIONS

End User Piracy: The installation of the software onto computers or terminals exceeds the user license allows.

Intellectual Property (IP): Copyrights, patents, trademarks, and trade secrets. Copyrights protect literary or artistic creation, ranging from books, articles, scripts, and audio and video recordings. Patents protect registered and determined inventions or discoveries that exclude others from making, using, offering for sale, or selling, and the examples include the composition of a new medication. Trademarks protect a companies’ name, products’ name, logos, slogans, or package designs. Trade secrets secure formulas, production procedures, and even business lists, and Coca Cola’s secret recipe is an example.

Internet Piracy: Piracy that is conducted or facilitated by the Internet where unauthorized creative contents are distributed.

IP Theft: Stealing law-protected intellectual property that reflects creators’ ideas, inventions, or creative expressions, in tangible or intangible format.

Piracy: The unauthorized use or reproduction of works that belong to another individual(s) or entity for the purpose of financial gain.

Reseller Piracy: When an individual or organization consciously produces multiple copies of the software with the intent of selling for profits.

Software Piracy: Unauthorized duplicating or distributing of copyrighted software with the intention to gain financially.

ENDNOTES

- ¹ According to the International Federation of the Phonographic Industry, there are four kinds of illegal activities that fall under the music piracy umbrella: physical music piracy, counterfeit, bootlegs, and Internet piracy.

² Like many other oft-used terms describing Internet-related crimes, such a term that includes the medium/instrument (Internet) carrying IP in its name usually distracts the discussions and thereby confuses people.

³ One of the four founders was later arrested for the conviction in 2012 in Cambodia.

⁴ According to the Business Software Alliance, a software industry trade association, there

are roughly 840,000 Internet sites partaking in the illegal selling of software as the real thing.

⁵ Megaupload at one point was the 13th most visit site online, according to Alexa.com. It was accounted for 4% of worldwide Internet traffic.

Secure Group Key Sharing Protocols and Cloud System

Vaishali Ravindra Thakare
VIT University, India

John Singh K
VIT University, India

INTRODUCTION

Secure group communication is an important research issue in the field of cryptography and network security, because group applications like online chatting programs, video conferencing, distributed database, online games etc. is expanding rapidly. Group key agreement protocols allow that all the members agree on the same group key, for secure group communication, and the basic security criteria must be hold. Many group key agreement protocols have been established for secure group communication.

Since the group generation processes takes many modular exponentiations and long time in generation of group key. For achieving higher security, group key protocol should be dynamic, means it should change for each new join or leave member, so that new member have not any knowledge about prior information. Therefore group key management protocol focusing on the group key generation efficiently. The authors have identified the research gaps in the existing protocols and these are communication, computation overhead while generating and sharing digital envelopes and security issues while sharing group key with encryption algorithms. These research problems in existing framework motivate authors to focus on security and efficiency of the system. Many practical systems have been proposed (Liu et al., 2014a, 2015; Pan et al., 2011; Sanchez-Artigas,

2013; Li et al., 2015) of which the most familiar one is the TGDH key distribution system. After analyzing the demand for sharing data with multiple users in groups by reducing computational complexity and for achieving productive benefits, an efficient solution is proposed in this paper.

Modular exponentiation is very expensive in computation of group key. The number of exponentiations for membership depends on group size as when the group size increased the number of exponents will also increase. Tree Based Group Diffie Hellman (TGDH) (Kim et. al., 2004) uses the concept of Diffie-Hellman key exchange with logical tree structure to achieve efficiency. The efficiency of TGDH is $O(\log 2n)$, where n is the group size. However, some extra overhead occurred in maintaining a perfect key tree balance. Skinny tree has lower communication overhead, but it increases computation. Burmester–Desmedt (BD) distributes and minimizes computation by using more messages broadcast. All these protocols using similar security properties including group key independence. From the broad study it is found that, tree-based CGKA (Contributory Group Key Agreement) methods are more efficient since they reduce the complexity from $O(n)$ to $O(\log n)$ while computing the new group key, where n is the group size. Consequently, this unit considers only the existing tree-based CGKA protocols.

BACKGROUND

Group key agreement protocols allow that all the members agree on the same group key, for secure group communication, and the basic security criteria must be hold. In 1994 Mike Burmester and Yvo Desmedt Proposed A Secure and Efficient Conference Key Distribution System (BD Protocol), In 2000 Group Diffie Hellman (GDH) was proposed by Steiner et.al., Skinny Tree (STR) Wong et al. 2000, ID-AGKA (Identity based authenticated group key agreement protocol) by K C Reddy and Divya Nalla in 2002, Kim et al. proposed TGDH (Tree Based Group Diffie Hellman) in 2004, In 2006 CCEGK was proposed by Szheng, Moreover in 2009 QGDH (Queue Based Group Diffie Hellman) by Hong S.

After understanding the real time issues in real time groupware applications like voice & video conferences, distributed computation over the insecure network.

(Zheng et al., 2007) Proposed a two round key agreement protocol for dynamic peer group (DPG). The protocol is proven secure against passive attack by using indistinguishable method. Moreover, both perfect forward secrecy (PFS) and key independence (KI) were achieved. Author's proposed protocol greatly reduces the computation complexity of each member, definite identification and time stamp are added to the protocol to effectively avoid replay attacks and it satisfies PFS, dynamic and it provides a session key for wireless group members due to which its messages are transmitted through broadcasting. Meanwhile, authors proved correctness, tolerance for passive attacks, secure against active adversaries in the random oracle model as the security and efficiency analysis of this protocol.

(Liu et al., 2013) Proposed a secure multi-owner data sharing scheme (Mona) for dynamic groups in cloud applications. The Mona aims to realize that a user can securely share the data with others via the un-trusted cloud servers, and efficiently support dynamic group interactions. In this scheme, a new user can directly decrypt data files

without pre-contacting with data owners, and user revocation is achieved by revocation list without updating the secret keys of the remaining users.

(Xue & Hong., 2013) proposed a novel secure group sharing framework for public cloud and it can take the effective advantage of cloud help by taking care that no sensitive data should be exposed to cloud provider and an attacker. It combines proxy signature, enhanced TGDH-based binary tree, proxy re-encryption as a protocol, using which the authors have achieved the objective. In this scheme, authors used TGDH with binary tree to negotiate and update the group key pairs with the help of cloud servers

(Jaiswal & Tripathi., 2015) Proposed an alternative approach to group key agreement, i.e., a novel queue-based group key agreement protocol, which uses the concepts of elliptic curve cryptography to reduce unnecessary delays, considers member diversity with filtering out low performance members in group key generation processes. After analyzing many prior group key agreement protocols like TGDH, STR, BD, and QBDH, they provide better security. They take more computational overheads. So, authors have used elliptic curve cryptographic technique that removes exponentiation to reduce computational overheads, and hence the results are better than that of the other group key agreement protocols.

Figure 1 shows the tree structure of CGKA, the management of secure communication among groups of participants requires a set of secure and efficient operations some protocols are better in communication cost some are in computation of secure group key while some are having security issues. These all protocols fall under CGKA (Contributory Group Key Agreement) scheme. CGKA is further again Divided into two sub categories:

Tree Based-CGKA

STR (Skinny Tree)

The STR protocol is modified to provide dynamic group operations. The protocol has a relatively

Figure 1. Tree structure of CGKA (contributory group key agreement) protocols

low communication overhead and is well suited for adding new group members. Robustness is easily provided. However, it is relatively difficult for member exclusion ($O(n)$ modular exponentiation). The GK = $g^{K_n} g^{K_{n-1}} \dots g^{K_2} g^{K_1}$. The STR is communication efficient and it is more secure against attacks specific to group communication

TGDH (Tree Based Group Diffie Hellman)

The first tree based CGKA protocol called TGDH was proposed in which key tree and DH protocol are combined to generate the group key. After comparison of TGDH with STR and GDH protocol. The TGDH is comparatively efficient in join events, and it is best in leave events. The TGDH is more efficient in both computation and communication than GDH. The 'Skinny Tree' (STR) employs the key tree concept used in TGDH. TGDH provides the most efficient group key agreement protocol. The protocol has low communication overhead and low computation overhead ($O(\log n)$ modular exponentiation). In addition,

TGDH provides robustness. The GK = $g^{g^{K_1} K_2 g^{K_3} K_4 \dots g^{K_n} - 3 K_n - 2 g^{K_n} - 1 K_n}}$

In every operation of TGDH (e.g., Join, merge, leave, and partition), every message uses the broadcast scheme, so authors implement the initialization operation in TGDH using a broadcast scheme. TGDH key management protocol for dynamic secure group data sharing In ternary tree with TGDH all group members are initially arranged as the leaves of ternary tree and three party TGDH generates the final group key. This generation of group key is done in two stages:

1. Up-flow stage,
2. Down-flow stage.

Consider two prime numbers p and q such that $q|p-1$ and size of p and q are large enough so that solving the discrete logarithm problem in G is infeasible computational, where G is a subgroup with order q of a finite field Z_p^* [2] g is the generator. Consider, Alice, Bob and Charlie are three users that generates a shared secret key between them.

Up-flow:

- Alice constructs a set $\{g^x \bmod p\}$ and send it to Bob.
- Bob constructs a set $\{g^{xy} \bmod p, g^y \bmod p, g^x \bmod p \text{ (received from Alice)}\}$. Bob sends this set to Charlie- Similarly, Charlie also construct a set $\{g^{xyz} \bmod p, g^{yz} \bmod p, g^{xz} \bmod p\}$.
- Here, $g^{xyz} \bmod p$ is a cardinal value and treated as a group key K . Where, x , y and z are random numbers assumed by Alice, Bob and Charlie respectively.

Down-flow:

- Charlie broadcast the remaining set element ($g^{yz} \bmod p, g^{xz} \bmod p$) to other members in a group i.e. Alice and Bob.
- Now, every members assumes their random numbers for computing the same group key.
- (Alice $\Rightarrow K: (g^{yz})^x \bmod p$ and Bob $\Rightarrow K: (g^{xz})^y \bmod p$).

Non Tree Based-CGKA

BD (Burmester-Desmedt)

The BD protocol (Burmester and Desmedt, 1994) supports dynamic group operations. The protocol has a relatively low computational overhead due to two modular exponentiations. However, it needs more message exchanges to generate GK. The $GK = g^{K1K2+K2K3+...+Kn-1Kn}$.

GDH (Group Diffie-Hellman)

It provides high security assurance (Cui et. al., 2014). However, it has a relatively high computation cost ($O(n)$ modular exponentiation) and is relatively hard to provide robustness. The $GK = g^{K1K2K3K4...Kn-1Kn}$

QGDH (Queue Based Group Diffie Hellman)

Figure 2 shows Queue-based Group Diffie-Hellman Entity Model (Hong S., 2009, Jaiswal & Tripathi, 2015). In Figure 2, a Group Controller Server (GCS) has a member information DB containing a current login member list, MAC addresses, IDs, Passwords, and Blind Key Queues (BKQ). If each member logs in to the GCS, then the GCS will validate his ID, password, and MAC (Media Access Control) address by checking his member information DB. After approving member's identification, all members start to generate a group key by sending his blind key to the GCS who collects all blind keys and store them into the Blind Key Queues (BKQ) in order of arrival. Then the GCS informs participants who will join the next level of the group key generation.

CCEGK (Communication-Computation Efficient Group Key Algorithm)

The CCEGK was developed for large and dynamic groups that combine two existing protocols such as EGK and TGDH (Lee et. al., 2003). It outperforms EGK, TGDH and STR protocols. CCEGK designed to provide both efficient communication and computation, addressing performance, security and authentication issues of CCEGK. An analytical comparison of all algorithms revealed eight similar methods: add, remove, merge, split, mass add, mass remove, initialize, and key refresh. Comparing the cost in terms of communication and computation, we found CCEGK to be more efficient across the board. With the advent of new arenas such as wireless ad-hoc and low powered distributed computing and communication devices, designers of group key encryption algorithms can no longer ignore communication in favor of computation or vice versa. In some environments the power cost of communication may be sufficiently high to warrant low cost communication protocols, whereas in other environments computation cost may be

Figure 2. Queue-based group diffie-hellman entity model

the dominant feature. CCEGK is a group key management algorithm based upon two preceding group key management algorithms, EGK and TGDH. By extending this previous work, CCEGK considerably improves both communication and computation costs of their related operations.

CCEGK, as do EGK and STR, always joins at the root of the tree, resulting in potentially far fewer sequential exponentiations. TGDH will join at the root only if the tree is a full tree, in an attempt to keep the tree more balanced. STR, on the other hand always has a skinny tree, where every internal node has one child that is a leaf.

CCEGK, as with EGK, merges the two roots of the trees, resulting in lower cost but a potentially more unbalanced tree. TGDH merges the shallower tree to the deeper one, or at the root, whichever creates the shallowest final tree. STR adds one tree to the bottom of the other.

SOLUTIONS AND COMPARITIVE ANALYSIS OF SECURE GROUP KEY SHARING PROTOCOLS

Group Key Management Operations

Throughout this chapter authors addressed several group key management operations used by

group key systems. The operations are described as following:

- **Initialization Operation:** This is the initial creation of the group key and organization of the key management infrastructure.
- **Join:** This operation brings a new member into the existing group.
- **Leave:** This operation is used to remove a member from the group.
- **Partition:** This operation, different from mass leave, occurs when a single group is divided into two or more component groups.
- **Merge:** This operation, as opposed to mass join, is used when another group is combined with the existing group to become a new group.
- **Key Refresh:** To prevent the secret key from becoming stale, it should be changed. Moreover, to prevent an adversary from breaking in, users should refresh the original key and generate a new secret key periodically.
- **Number of Rounds:** This is a generic time unit used to compare the number of steps taken in different operations. The algorithms often require synchronization between rounds; therefore, this number

Table 1. Communication and computation cost analysis of tree based-CGKA protocols

Tree Based CGKA Protocols		Communication Cost		Computation Cost
		Rounds	Messages	Exponentiation
STR	Join	2	3	4
	Leave	1	1	$\frac{3n}{2} + 2$
	Partition	1	1	$\frac{3n}{2} + 2$
	Merge	2	k+1	3m+1
TGDH	Join	2	3	$\frac{3n}{2}$
	Leave	1	1	$\frac{3n}{2}$
	Partition	$\text{Min}(\log_2 p, h)$	2h	3n
	Merge	$\text{Log}_2 k+1$	2k	$\frac{3n}{2}$

becomes important when taking synchronization time into account.

- **Number of Messages:** This is the sum of all unicast messages and broadcast messages. users use this number to determine the total time of communication in an underlying broadcast network.
- **Number of Exponentiations:** During an operation there will be a series of computationally expensive cryptographic operations (such as modular exponentiation used in the DH algorithm). The algorithms in the literature often require the results of one cryptographic operation prior to the execution of another. This metric represents the worst case scenario, the longest sequence of dependencies of these costly cryptographic operations in the operation.

The authors of this article have analyzed many existing group key agreement protocols like TGDH, STR, BD, QBDH and CCEGK.

They provide better security, but some take more computational overheads, some take more communication overhead. So, Following Table 1 shows communication and computation cost analysis of Tree Based-CGKA Protocols and Table 2 shows communication and computation cost analysis of Non Tree Based-CGKA Protocols.

FUTURE RESEARCH DIRECTIONS

Recently, group data sharing (GDS) has attracted significant attention for its wide applications in many different fields. A GDS can be seen as a special dynamic and distributed group, so the secure communication is essential in it. Surely, the most common method is to encrypt messages with a group key only shared by the included nodes, so that those outside the group cannot decode the encrypted messages. Thus, the protocol to achieve the group shared key is crucial, which users often name the *key agreement protocol*.

Table 2. Communication and computation cost analysis of non tree based-CGKA protocols

Non Tree Based CGKA Protocols		Communication Cost		Computation Cost
		Rounds	Messages	Exponentiation
BD	Join	2	$2n+2$	3
	Leave	2	$2n-2$	3
	Partition	2	$2n-2p$	3
	Merge	2	$2n+2m$	3
GDH	Join	4	$n+3$	$n+3$
	Leave	1	1	$n-1$
	Partition	1	1	$n-p$
	Merge	$m+3$	$n+2m+1$	$n+2m+1$
QDGH	Join	2	$2n-2$	$\frac{3(\log_2 n)}{2}$
	Leave	1	$2n-2$	$\frac{3(\log_2 n)}{2}$
	Partition	1	$2n-2$	$3(\log_2 n)$
	Merge	2	$2n-2$	$\frac{3(\log_2 n)}{2}$
CCEGK	Join	1	2	1
	Leave	1	1	$3h-3$
	Merge	1	N	$n-1$

Over the years, numerous excellent key agreement protocols for dynamic peer group have been proposed, such as the GDH, TGDH and extended STR protocols. However, not all of them are communication efficient when applied to cloud networks. All of these have better security built-ins. Now a day in every fields cloud computing is used, health care, IT industries, small and medium enterprises (SMEs). So, The scope of these protocols is everywhere widely growing because of the requirements of the changing world towards cloud computing. There will be various kinds of requirements of healthcare organizations, as healthcare organizations are the primary priority in every country, Healthcare clouds must be as

secure as possible. According to the organizations requirements healthcare cloud groups will be formed for the secure communication between other organizations in healthcare and these protocols will take care about security and confidential data, communication and computation overheads.

CONCLUSION

Data sharing in cloud environment by forming groups is considered as a common approach. But secure data sharing in groups is still a challenging issue for the researchers. There are many frameworks available to share data in groups in

the previous researches listed in above discussion of this chapter, after analyzing the existing frameworks drawbacks; it is found the tree based CGKA protocols are more efficient than others. From Table 2, TGDH is better protocol for secure group data sharing and it can be used in healthcare cloud applications. From Table 3, CCEGK protocol is better but it is non-tree CGKA protocol but its communication and computation overhead cost is lesser than the BD, GDH and QGDH protocols.

KEY TERMS AND DEFINITIONS

Cloud Computing System: Cloud computing is a model for delivering information technology services in which resources are retrieved from the internet through web-based tools and applications rather than a direct connection to a server.

Computational Complexity: A mathematical characterization of the difficulty of a computing group key which describes the resources required by a computing machine to compute the group key. The mathematical study of such characterizations is called computational complexity theory and is important in many branches of theoretical computer science, especially cryptography.

Proxy Re-Encryption: Proxy re-encryption schemes are cryptosystems which allow third parties (proxies) to alter a ciphertext which has been encrypted for one party, so that it may be decrypted by another.

Proxy Signature: Proxy signature, which allows an original signer to delegate his/her signing right to another party (or proxy signer), is very useful in many applications.

Security of Internet–, Intranet–, and Computer–Based Examinations in Terms of Technical, Authentication, and Environmental, Where Are We?

Massoud Sokouti

Mashhad University of Medical Sciences, Iran

INTRODUCTION

Over the past decades, the use of Internet and its various applications in several environments such as academic communities and industries has been dramatically increased. Fundamental aspects of these applications are commonly related to sending and receiving small or large amounts of data through the local or global network communications. Transferring data over the insecure tunnel of Internet requires applying security services when especially the sensitive data are involved. The main security services are confidentiality, integrity, and availability namely called the CIA triad. The recent advancements in computer networking lead many technologies to be solely or partly upgraded their traditional environments into e-environments and hence, dependent on electronic-based objects such as e-mail and digitalized records and images. The security of shared or archived data or information personally or in organizations are vital and important due to the development of information science in modern society with everyday dramatically increase. Because of its rapid changing nature driven mostly by technology such as smart phones and development of new virtual communities, there are several demands for generating information systems in which security properties play vital roles. By considering these developments, the

e-learning parts of academic communities (i.e., online education) at universities have been affected in order to keep up with the knowledge innovation and they also provide some of their degrees and courses in a distance-based structure by taking the advantage of web-based infrastructures such as LMS (Learning Management System) and MOODLE (Modular Object- Oriented Dynamic Learning Environment). And, this makes the research areas open for modern education era to conduct paperless examinations by providing more security and efficiency. Although, this technological transition in the educational section is to some extent valuable and time effective, however, in most cases the evaluations and examinations of examinee are carried out and monitored in a supervised manner. Precisely speaking, for taking an exam in a traditional examination environment generally examinees, proctors, professors, pen and exam papers and a secure or isolated examining hall are included. For implementing such exams in a distance- or electronic-based model, many security issues whether they are technical or environmental are raised and essential to be resolved. In this regard, an examinee may take the exam alone at home; the professor makes the exam questions and sends them to a web server; the proctors' role can be performed supervised or unsupervised;

the sufficient security measurements should be in place of e-exam's environments.

As of now, providing the most of security services for unsupervised e-exams is still in its infancy and needs much of attention to be taken in to consideration, however, most of technical and communication-based security issues have been addressed in abundance.

In this chapter, the literature researches carried out on potential security aspects of conducting a robust secure e-exam are discussed, then their pros and cons with respect to their provided security services are evaluated and reviewed, and finally a hybrid security model for satisfying most of security properties will be proposed as a secure e-exam model for all conditions along with negotiating future directions.

BACKGROUND

For managing and conducting any types of e-exam systems, literature researchers have performed diverse studies considering special security aspects of them whether they are supervised or unsupervised including technical (e.g., networking, question generation, servers, clients), examinee authentication and identification (e.g., passwords, tokens, and biometrics), environmental monitoring (e.g., webcams, microphones) for preventing possible cheatings during the examination period. Nowadays, for universities providing distance learning courses and degrees are getting epidemically widespread and educationally of much of interest over the world. To survey the current position of state of art related to online exams considering the security aspects, the SCOPUS database is searched and reviewed with the keywords “online” AND “exam” AND “security” in which 19 out of 49 were filtered out based on their relevant contents (i.e., by using title and abstract) for this study. However, one out of 19 was proposed as a web tool for teachers and did not discuss the security aspects of the online examinations (Castillo-Ramoran, 2008).

In order to prevent various types of cheatings, some of the supervised approaches are carried out by employing video and audio devices such as webcams and microphones, biometric recognition tools, manually controlling the port and IP of the connected network devices most of which are relevant case studies for their classrooms in the local area networks (LANs) (Bari, Sullivan, & Blair, 2004; Jung & Yeom, 2009; Savulescu, Polkowski, & Alexandru, 2015). However, these environments are monitored manually via instructor-student networking communications.

From technical point of view and assuming that the only security problems can be carried out by outside attackers, Ming-Ming and Yan have proposed a simple security environment by considering only the data encryption by using triple DES algorithm and secure communication channel (i.e., virtual private network (VPN)) for secure connection of students and stopping the outside attackers (Ming-Ming & Yan, 2013). Also recently, a simple secure computer based examination was also carried out using the B/S structure (Singh & Tiwari, 2016). Another two approaches were conducted as frameworks in which the security countermeasures and the access control to the database servers (e.g., SQL server) were considered (Darong & Huimin, 2010; Haiyan, GHong, Lijun, & Jie, 2014).

For physically distance monitoring of a classroom or a room in which online exams were conducted, an environmental based secure framework was proposed by Stocco and colleagues by incorporating sets of logical and physical sensors (Stocco, Otsuka, & Beder, 2012). Employing the logical architecture of object oriented business application which has five layers including interface layer, interface control business layer, data access, and data storage and management will also bring some advantages (Basar & Haji-zada, 2014). These pros are summarized in scalability, flexibility, and security (Basar & Haji-zada, 2014). So, only the network access manages to stop all types of attacks applied on local and global networks. In other study, the authors have considered four

phases (i.e., registration, examination, marking, and notification) for providing security properties (Giustolisi, Lenzini, & Bella, 2013). In these phases, eligibility, identification, authorization, authentication, authorship, integrity, anonymous marking, mark integrity and privacy are of great importance. Another type of supervised framework is the study which incorporates both teacher and manager to monitor and manage the students during the online exams by considering security properties such as authenticity, privacy, secrecy, receipt of exam answer and copy detection (Castella-Roca, Herrera-Joancomarti, & CDorca-Josa, 2006). During the technological improvements, tablets with their built-in cameras took researchers attentions to develop secure apps for their courses (Gramoll, 2015).

The remaining literature studies have discussed the security properties of the online based examinations in terms of cryptographic algorithms in order to authenticate exam candidates (Karim & Shukur, 2015). Karim and Shukur have demonstrated a review on the list of various authentication methods derived from different databases including Scopus, IEEE Xplore, Springer link, Science Direct, ACM, and Google Scholar (Karim & Shukur, 2015). Some of the samples of the review performed by Karim and Shukur took the advantages of uni or multi authentication methods using biometric properties along with/without username and password each of which have their own strengths and weaknesses. The biometric features include palm print (Al-Saleem & Ullah, 2014), keystroke dynamic, voice recognition, stylometry, face recognition, iris recognition, mouse movements, and hand writing (Karim & Shukur, 2015). Besides these, use of challenge questions (Ullah, Xiao, Barker, & Lilley, 2014) and IP addresses with timestamps (Gao, 2012) are other methods to mention a few.

A typical multimodal biometric technology embedded for authenticating the candidates was proposed to enhance the security of the users' authentication (Asha & Chellappan, 2008). This dynamic based authentication incorporates the

physiological (fingerprint technology) and behavioral (mouse dynamics) properties of the user by means of a mouse device with built-in fingerprint scanner (Asha & Chellappan, 2008). An interactive and secure e-examination unit (ISEEU) was proposed by Sabbah and colleagues where its one-on-one supervised based framework makes it good for continuous authentication using webcams during the video calls in order to reduce the potential user cheatings (Sabbah, Saroit, & Kotb, 2011) by considering that for having a secure environment three user security properties including identity, authentication, and presence should be checked continuously. Moreover, checking the presence via tracking the timestamp having been spent in front of the computer have also discussed elsewhere (Agulla, Rifon, Castro, & Mateo, 2008). It has also been shown that using the keystroke recognition on long-text input under different conditions has less accuracies while different devices in terms of laptop and desktop pc are used which is not applicable for real world conditions (Villani et al., 2006).

Although, these available research papers have proposed, assessed and emphasized on different aspects of security issues related to electronic-based or online exams, however, there are no robust models or protocols to satisfy all security aspects.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Based on the abovementioned literature articles published in the theme of online-exams in terms of security issues, it can be deduced that all of them are not proposed as a whole response for providing and considering all aspects of security. Some of them were only technical based and required information security protocols and standards for a network engineer to meet the essential security measures. On the other hand, several algorithms and approaches were proposed in order to authenticate the user by incorporating several aspects of

authentication whether they were used in a uni or multi factor authentication using properties for “What you are” (i.e., it can satisfied by providing biometric features), “What you have” (i.e., it can be met by a token), and “What you know” (i.e., username and password or multiple question challenges). However, more terms also need to be considered such as “Where you are” and “What you do” that can be checked by monitoring the target environment using video calls, surveillance cams and web cams. Most of recent studies do only satisfy one, two or three out of abovementioned terms which are not a complete answer for having a secure online-examination environment.

These three categories including technical, authentication, and monitoring of the environment are studied several times but not all together in the literature by its special category. However, they have still their own threats and issues in terms of security and still need more researches on proposing new cryptographic algorithms for identification and authentication in different situations.

SOLUTIONS AND RECOMMENDATIONS

By considering the strengths and weaknesses of the approaches studied in the themes of three categories, none of the categories alone by themselves can be enough for meeting the required security properties that have been discussed before. So, for having a comprehensive security model which includes all five security services shown in Figure 1, it is required to merge all three categories to one and took the advantages of the resulted model in all online exams whether they are taken in a local or global network. By incorporating all of three categories with various combinations, one may conclude that the current model will satisfy all the security properties required for stopping the users’ cheating in any types of local positions or internet based conditions.

In other words, by implementing the unsupervised online exam environments one must be

Figure 1. Required security services for a secure online examination

assured of that all of the security services listed in Figure 1 are in place. For example, providing technical security is solely depending on the local or global administrators’ opinion in order to stop any types of insider (i.e., student, manager, and teacher) and outsider attacks, denial of services (DOS), distributed denial of service (DDOS), and replay attacks by setting up required security countermeasures such as securing the network communication channels (VPNs), data encryption, tracking timestamps, and etc. For the sake of user authentication depending on the situation, username and passwords, tokens, and multi biometric (e.g., fingerprint, mouse dynamics) features are required as one multi authentication package. And finally, the security needs required for an unsupervised situation, several environmental monitoring devices should be employed such as behavioral and movement sensors, webcams, and environmental microphones.

FUTURE RESEARCH DIRECTIONS

Nowadays, the shadow of security can be seen spreading its wings all over the technology ranging from the intelligent tablets to professional

laptops and new car products. The improvements covering all aspects of an object which may include the hardware and technology, software and applications, and cryptographic algorithms and their assessments (i.e., encryption, decryption, digital signatures, key generations) (Bahar, Sokouti, & Sokouti, 2010; M. Sokouti, Sokouti, & Pashazadeh, 2009; Massoud Sokouti, Sokouti, Pashazadeh, Feizi-Derakhshi, & Haghipour, 2013; M. Sokouti, Sokouti, Pashazadeh, & Khanli, 2010; M. Sokouti, Zakerolhosseini, & Sokouti, 2014) will have extensive effects on the performance of online exams in terms of security.

Moreover, in the future studies it is essential for the authors to provide a web site or database server of their implementations as it can be seen widely in the bioinformatics and systems biology realm (B. Sokouti, Church, Morris, & Dastmalchi, 2015; B. Sokouti, Rezvan, & Dastmalchi, 2015, 2016; B. Sokouti, Rezvan, Yachdav, & Dastmalchi, 2014). This will help the researchers assessing their new conducted model or algorithms with previously published approaches.

The last but not the least, it is sometimes recommended to assess and find out the shortcomings of the existing methodologies in order to improve them rather than implement an unknown method with high risks of security issues.

CONCLUSION

In this chapter, security aspects of online exams in different situations were discussed. Three categories of the research interest including technical, authentication methodologies, and environmental monitoring were also covered in terms of both supervised and unsupervised. Moreover, based on the shortcomings and weaknesses in all three categories, a new security model can be carried out considering various combinations of these categories to reach a gold standard and a secure framework for online exams without any types of cheatings.

KEY TERMS AND DEFINITIONS

C

Authentication: A process for knowing if someone who he is declared to be.

Availability: A guarantee for an information resource being accessed all the time by authorized users. CIA Triad: There most required ones for security services (i.e., Confidentiality, Integrity, and Availability).

Confidentiality: A security service equivalent to privacy which can be achieved by encrypting the message using a cryptographic algorithm.

Identification: It is related to the identity of a person who claims about it.

Integrity: An assurance for information not being altered or changed during the communication.

Online Exam: A type of exam which can be taken overseas or locally with or without manual supervision.

A Three-Vector Approach to Blind Spots in Cybersecurity

INTRODUCTION

With the increased use of network technologies (Clements & Kirham, 2010), cybercrime is on the rise. PricewaterhouseCoopers estimates that 120,000 cyberattacks occur daily (PwC, 2016). There is a need for cybersecurity throughout society. Cybersecurity is defined as “the organization and collection of resources, processes, and structures used to protect cyberspace and cyberspace-enabled systems from occurrences that misalign de jure from de facto property rights” (Craigen, Diakun-Thibault, & Purse, 2014). It is also the measure of preparedness including recovery, protection, and triage against the losses caused by cyberattacks (Maughan, 2010).

Cybersecurity is key for protecting valuable assets such as intellectual property, virtual currencies, and industrial control systems (Kritzinger & Solms, 2010; Smith & Rupp, 2002). However, cyberattacks are often successful due to “blind spots,” which refer to various biases and preconceived information that affects organizational and human decision making (Heuer, 1999; Pronin, Lin, & Ross, 2002), leading to unawareness of malicious activity (Boehm & Turner, 2005). It

is important to understand how to mitigate all blind spots, particularly those that can lead to massive economic losses (Flowers, Zeadally, & Murray, 2013).

The objective of this chapter is to investigate eight cyberattack cases (“attack scenarios”) from the viewpoint of “the core vectors” which include economic, technological and psychological perspectives to blind spots. While previous research has viewed core vectors in isolation from each other (Baker, 2014; Garfinkel, 2012; Singer & Friedman, 2014), this chapter focuses on how to mitigate blind spots in cybersecurity by using a holistic three-vector approach. The holistic view to cybersecurity has been suggested by many authors (Emami-Tabatabaie, Amoui, & Tahvildari, 2013; Hua & Bapna 2013; Hughes & Cybenko, 2013).

Section one provides an overview of cyberattacks and blind spots that enable attacks. Section two discusses core vectors conceptualized as psychological, economic, and technical perspectives to blind spots. Sections three and four discuss research methods and eight scenario cases. Section five presents a summary table of the cases included in the sample. Finally, sections six and

seven discuss future research avenues and implications to practice.

BACKGROUND

Han and Dongre (2014) list political, economic, and socio-cultural motives as primary motives for cyberattacks, and emphasize that attackers can be organizational insiders or outsiders. Political motives include cyber terrorism against foreign nations or multinationals (Hua & Bapna, 2013) and ethically fighting for justice and human rights (Gandhi et al., 2011). Other motives may be plain entertainment. Regardless, there is a propensity for harm when cyberattacks occur. Understanding what enables these attacks enables mitigation, and will contribute to the theory on blind spots in cybersecurity (Chen, Huang, Xu, & Lai, 2015; Nathan & Petrosino, 2003).

Blind spots are dangerous because they are about biases and preconceptions (Pronin et al., 2002). Humans tend to interpret new information so that prior conclusions remain intact. A 2012 survey by the National Cyber Security Alliance (NCSA) and Symantec revealed that 83% of small U.S. companies did not have a formal plan for keeping their business cyber-secure although over 70% responded that a safe and trusted Internet is critical to their day-to-day operations. A total of 76% thought that their company was safe from cyber-security breaches.

Given that blind spots are inevitable, there is a need to develop more efficient means to mitigate them. Thus, it is critical to understand how (i) the business, (ii) the psychological, and (iii) the technological perspectives might help organizations and individuals to recognize and avoid blind spots. This core vector thinking is supported by the cybersecurity assessment factors by Gavins and Hemenway (2010) and the categorization of attacker motivations by Han and Dongre (2014). Combining vectors enables a comprehensive analysis of past cyberattack scenarios in order to mitigate blind spots.

PERSPECTIVES TO CYBERSECURITY

C

Cybersecurity should be examined through psychological, economic, and technological vectors. Wiederhold (2014) argues that psychology in human nature is the weakest link in cyberspace. Although technology is sophisticated, humans still fall victim to social engineering (Bauer & van Eeten, 2009). Economic factors are important as computers are infested with malware to enrich attackers, and victims ponder associated costs (Hua & Bapna, 2013).

Psychological Vector

Human factors affect cybersecurity the most (Baker, 2014), and when cyber threats are not understood or are ignored, adverse consequences accrue. What people perceive of risks affects how they behave (West, 2008). The 2012 NCSA/McAfee survey showed that 64% of Americans feel their smartphone is safe from cyberattacks even though they had not installed any security software.

Sukamol and Markus (2008) argue that many individuals make security decisions from a simplistic understanding of risk. In organizations, risk has focused on technology, but firms are now expanding their technology-centered perspective to include people and processes (PwC, 2016). Heuer (1999) notes that it takes more information and more unambiguous information to recognize an unexpected phenomenon than an expected one. Moreover, Cebula and Young (2010) argue that many people use the same combination of user ID and password for different information systems because of human memory limitations thereby creating a huge risk to cybersecurity.

The psychological vector is associated to human thinking and cognitive limitations affecting decision making. Humans are especially prone to blind spots when it comes to complex systems like law, politics, or cyberspace. A typical user may not be able to identify an email phishing attack or

a cloned website; whatever captures their minds as close enough is good enough. Thus, “unknown unknowns” associated with complex systems make an intellectual blind spot (Brotherton, 2015), and human understanding of risk plays a big role in fostering secure actions.

Economic Vector

Different industries are exposed to different cyber threats. The banking and finance sector is most concerned about financial fraud, and 65% of the frauds are cyberspace related (Chakrabarty, 2012). The information and communication technology sector is most concerned about illicit access to email and other electronic communications, because they offer access to trade secrets and business-sensitive information potentially harming the whole value chain (PwC, 2016). The insurance sector is primarily concerned about financial losses due to sensitive information being exposed unintentionally. Attackers clearly have financial motives and the victim normally suffers economic losses. Globally, the financial loss from cybersecurity incidents is increasing by 34% annually (PwC, 2016).

Unfortunately, individuals and organizations decide on cybersecurity investments under economic constraints such as limited budgets (Heuer, 1999). Although the increased engagement of the Board of Directors has impacted a boost in security spending (PwC, 2016), the financial cost attributed to cybersecurity investment is seen as huge by most businesses. Major issues among businesses is the inability to devise a cybersecurity investment strategy and the organizational inability to invest in the necessary personnel and processes to guard against attacks. Security risks can be mitigated through understanding one’s own vulnerabilities and the motivations of cybercriminals.

Supply chain partners are also dangerous. More than two-thirds of companies in the automotive industry attribute security incidents to partners such as resellers that have trusted access to their internal networks and data (PwC, 2016). However,

security checks for such partners are normally not practiced. The 2012 NCSA/Symantec survey shows that two-thirds of small companies are not protecting nor letting the partners know of their cybersecurity practices. Companies that have not suffered an attack may not know where to prioritize their cybersecurity investments, while companies that have suffered an attack are better handling security gaps and investing wisely.

Technological Vector

It is often assumed that technically inclined individuals have the knowledge to solve cybersecurity issues. However, the responsibility of handling security issues is not purely an IT department concern, but is everyone’s responsibility (Kritzing & von Solms, 2010). This raises the question of whether technology is a solution. West (2008) argues that sophisticated technology does not decrease system vulnerabilities, and that the more complex the technology the more vulnerabilities. Although organizations and individuals may use technology to avert attacks, they cannot guarantee immunity.

Many network security solutions, such as firewalls, are automated background processes (Garfinkel, 2012). However, cybersecurity requires users or operators to act appropriately; the lack of network security understanding may result in abuse of privacy and security (Singer & Friedman, 2014).

Simpler designs may help in developing technology with fewer security vulnerabilities. A system with many features and functionality is more likely to be compromised (Saltzer & Schroeder, 1975). It is important to check access and objects continually, enforce automatic security updates, and provide multiple levels of security so that if any bit is compromised, there is a safe alternative. Encryption makes it more difficult for data to be compromised, and technical alert systems can be used to prevent or mitigate unwanted occurrences (Shapiro & Cohen, 2007). However, technological

risks will never be totally eliminated as attackers shift to targeting vulnerable mobile technology.

METHODS

This study analyzes eight scenarios of successful cyberattacks. These scenarios occurred between 2007 and 2013, and the information used was collected from various online news websites. Possible vulnerabilities of each cyberattack is elaborated from the perspective of psychological, technological, and business vectors. Blind spot theory recognizes that people tend to focus on their perceptions of relevance, yet there are blind spots in regard to what people consider irrelevant or “unknown unknowns” (Taleb, 2012). These vectors provide an understanding of the enablers of blind spots; had these vulnerabilities been identified and addressed before a cyberattack, threats could have been mitigated and attacks avoided.

The analysis makes use of cybersecurity operational risks by Cebula and Young (2010), according to whom actions of people can be deliberate (fraud, sabotage, theft) or accidental (mistakes, errors), or a lack of action. Increased risk can also result from technology failures (systems design, specifications, and complexity; software configuration, settings, and practices; hardware capacity and obsolescence). Moreover, failed internal processes (problems in the internal business process flow, documentation, and alerting), process controls (status monitoring), and supporting processes (staffing, training, funding) affect the ability to implement, manage, and sustain cybersecurity. Finally, external events (dependencies on service providers, economic conditions) may result in risks.

FINDINGS

This sections summarizes eight cybersecurity incidents; the findings from the perspective of the three core vectors are emphasized with brackets.

- C
U. S. Banks: In September 2012, there was a series of Distributed Denial of Service (DDoS) attacks on major U.S. financial institutions, including JPMorgan and Citigroup. Virtual private web servers were used to flood the online banking system with junk email, attacking vulnerable web applications. The high volume of Internet traffic made the websites unavailable and resulted in client disruption. Iran was suspected to be the attacker to retaliate for the economic sanctions from the U.S. and its Arab allies. The banks assumed their servers were secure but discovered otherwise when they were attacked (psychology), although the technical functionalities of the hosted servers worked according to design (technology). The attack failed to affect the core of the business (business).
- Mat Honan:** In August 2012, Mat Honan’s entire digital life was destroyed by a hacktivist group who called Applecare customer tech support to obtain a temporary password for Honan’s me.com email using his billing address and last four digits of the credit card for identification. They found Honan’s billing address by searching his web domain information and received the last four digits by calling Amazon.com and requesting to add an additional credit card to Honan’s existing account. Although hackers failed to pass security questions, they were able to reset Honan’s AppleID password. His iPhone was disconnected from the Internet and iCloud login disabled, his twitter and Gmail accounts were deleted, and all his Apple devices were remotely erased. Honan had daisy-chained his Google and iCloud accounts using the same email prefix and did not have two-factor authentication for convenience reasons (psychology). The ‘Find my Mac’ application, a supposedly helpful feature, turned into an attacking tool used to wipe out Honan’s details (technology). Apple

violated their internal security processes and Amazon.com made access to sensitive information too easy for the sake of business and customer convenience (business).

- **Dalai Lama:** In 2008, the Office of His Holiness the Dalai Lama (OHHDL) sent out a confidential email to an unnamed country who was later warned by the Chinese government not to host the Dalai Lama. Investigations revealed infiltrations into the OHHDL's system. There were several unauthorized logins into email accounts from IP addresses belonging to Chinese and Hong Kong providers. The hackers composed emails that appeared to come from the OHHDL, causing recipients to visit malicious websites. Using phishing, the hackers were able to install rootkits on computers in several embassies, foreign ministries, and organizations and download sensitive data. Obviously, human thinking assumed it was safe to open these emails and click the links (psychology). OHHDL's web service was not encrypted and the vulnerabilities in office software allowed malicious content to be downloaded (technology). Organizations affected by the attack focused on their core processes and did not evaluate the potential loss of data or information due to their unsafe practices (business).
- **Koobface:** The Koobface worm has terrorized users of social media since 2008. Infection allowed hackers to access users' sensitive banking information and passwords. They aimed at users with invitations to watch a funny or sexy video. Those who clicked the link got a message to update their computer's Flash software, which began the download of the malware. Victims' computers were drafted into a network of infected computers, and were sent advertisements of fake antivirus software. Also, their web searches were hijacked and the clicks delivered to unscrupulous marketers. The group made money from people

who bought the bogus software and from unsuspecting advertisers. Koobface checks the user's Internet cookies to identify the social network the user has access to. Thus, they were able to send messages to the networking site for the user and there was no need to create a fake account on the social networking site (technology). They also capitalized on their victims' unwise click choices and the trust between the user and their social network contacts to increase the rate of malicious infection (psychology). More users, more traffic, more revenue is the pattern of thought of social media sites, and security that would prevent this kind of abuse comes later (business).

- **Cutting Sword of Justice:** Aramco is Saudi Arabia's largest oil and gas firm with affiliates all over the world. In 2012, Aramco's computer network was infested with a replicating virus Shamoon that affected its business process and caused the loss of data. Shamoon infected over 30,000 computers and caused a major disruption to the firm's business. It took almost two weeks to recover from the effect of the attack. The virus activates at a particular time, displays an image of a burning American flag and then sends reports of information to the attacker; moreover, files can be deleted from infected computers. The effects of the Shamoon can cause a firm to lose its Intellectual Property. Both an anti-oppression group and the Cutting Sword of Justice group took responsibility for the attack. The virus only affected computers used for Aramco's enterprise activities, not those used for oil production (technology). Thus, an in-house security issue may be involved (psychology). Surprisingly, there was no backup done for the drilling and production data during the period of the attack (technology). Later, Aramco invested heavily on cybersecurity and fast recovery from similar situations (business).

- Target:** The U.S. retailing company Target was attacked in late 2013. The attack was enabled by a malware planted in their point-of-sale terminals that allowed hackers to steal customers' information from the magnetic stripe of millions of debit and credit cards. The hackers accessed Target's network through a third party that had access to the network because they were monitoring the energy and temperature in stores for fluctuations in temperature that might affect the shopping experience (psychology). The hackers accessed the third party network using an email malware. Target's information system was not upgraded to work with the EMV chip technology that would enable them to read card information in an encrypted format (technology). Target had worked with Visa for over ten years to introduce smart cards, which would limit fraud by encrypting sensitive data contained on the card. However, they discarded the project after spending tens of millions because it was cheaper to issue and accept traditional magnetic-stripe cards than credit cards with silicon chips (business).
- Spamhaus:** In 2013, Spamhaus, an anti-phishing group, added Cyberbunker to its public black list, suspecting Cyberbunker to be an avenue of spam. Cyberbunker was a commercial Internet Service Provider with apparently undisclosed and shady activities. After Spamhaus blacklisted Cyberbunker, they experienced a severe DDoS against their email and web servers making it impossible for anyone to access their website. Soon thereafter, the spokesman of Cyberbunker, who was arrested, said "Spamhaus had too much control in determining and in deciding what spam is and what isn't". He operated within a mobile computing van from a well-equipped bunker and the attacks were generated by swarms of computers known as botnets (technology). After his arrest, there was an anonymous demand for his release, adding that if he were not released, there would be a larger attack. Since Cyberbunker felt hurt by Spamhaus, they decided to hurt and attack Spamhaus in return (psychology). Spamhaus was doing their job by listing those hosts who they felt were a spamming threat. Cyberbunker, on the other hand, was also pursuing their business interests by allowing spamming services to be hosted on their servers (business).
- New York Times (NYT):** In 2013, hackers were able to access every employee's password. The attack was achieved through spear-phishing where the hackers emailed malicious attachments or links to employees. Once an employee clicked on the email or link containing the malicious code, the hackers were able to install a remote access tool which aided them to extract data, passwords, images, keystrokes, documents, computer webcam and microphone recordings. The hackers focused on reporters who were preparing investigative reports on how the Chinese Prime Minister's family had gained their billion-dollar fortune from questionable business dealings. The hackers, assumed to be Chinese, wanted to determine the writers' sources of information for these reports. The attackers installed malicious software for a period of three months, during which time the firewall and antivirus program only discovered one instance of the presence of malicious software and had it quarantined. Hackers no longer focus their efforts in attempting to break firewalls, rather they capitalize on the social lapses of an unassuming human who will click on suspicious links and files received by email (psychology). Hashed passwords were made available for employees to make it difficult to steal their

passwords, but rainbow tables used by hackers nullify the security (technology). The NYT relied on a security provider to combat malicious threats while focusing on their own core business; however, no provider can mitigate all hacker exploits of human vulnerabilities (business).

A THREE-VECTOR APPROACH

The scenario analysis used three perspectives to blind spots in cybersecurity: (i) psychological (limitations of the human mind), (ii) technological (critical flaws and the need for secure

technology), and (iii) business (commercial logic behind attacks and security investments). Table 1 provides a combined three-vector approach to attack scenarios in order to illustrate blind spots as enablers of cyberattacks.

The resulting eight blind spots explain how human cognitive limitations; technological exploitation of vulnerable information systems; and economic motives of attackers lead to cyberattacks towards under-resourced. The eight blind spots are identified in Table 1. The blind spots were derived from a multi-vector analysis, providing a more holistic view compared to traditional approaches to cybersecurity risks.

Table 1. Blind spots and their mechanisms identified from the eight scenario cases

Example	Blind Spot	Mechanism of Enabler
U.S. Banks	Internal focus	Emphasis on digital technology that protects core operations and systems and secures internal processes (prevents hacking aimed at fraud and theft) allows attackers to harm non-core activities by targeting the outside interface (DDoS to prevent customers from entering a bank website)
Mat Honan	Convenience first	Allowing the customer to turn off critical security features and ignoring corporate security procedures in favor of customer convenience allows attackers to exploit holes, especially when the customer links social media accounts and login credentials for convenience
Dalai Lama	Habitual aspect	Office solutions have security vulnerabilities, and the attacker can exploit the victims' habitual aspect for unauthorized access to their systems
Koobface	Hedonistic enjoyment	The attacker is able to lure victims to click malicious files while they search for funny and entertaining content; installed malware is configured to spread through the victim's online social networks arising from a human need for social interaction and social enjoyment
Cutting Sword of Justice	Insider sabotage	Sabotage is driven by political or economic motives, and may require an insider who is able to contaminate the victim's systems and hinder their ability to recover from the attack; sabotage may be based on deterrence and creates harm even when aimed at the victim's non-core activities
Target	Wrong priorities	Wrong priorities for the sake of business and smooth operations, such as customer convenience, costs savings and functionality before technical security, as well as the unnecessary technical connection between core systems and supportive systems expose organizations to cyberattacks
Spamhaus	Egotistical behavior	Egotistical behavior of actors may spark cyber warfare, where both parties feel that their actions are justified; one side's under-evaluation of the other side's narcissistic motivation (i.e. revenge) and subsequent actions exposes them to large-scale and systematic full-frontal cyberattacks
NY Times	Technology effect	Overreliance on technology is dangerous if organizations and people believe a single technology prevents all kinds of cyber threats; however, such one-stop technology does not exist, and even the most complex security solutions are useless when "the keys to the lock" are easily accessible

FUTURE RESEARCH DIRECTIONS

Many individuals and organizations guard themselves against cyberattacks; yet some are affected by the lack of implementing sufficient safe practices. In lieu of this, there are newly devised and sophisticated avenues of attacks that are highly dynamic. It would take substantial effort to provide guidance to respond to all avenues. Thus, this chapter addresses ‘what perspectives can be used to identify blind spots and how the perspectives can be combined to help us mitigate blind spots?’

The examined scenarios showed that attacks could be averted or mitigated, if the victims focused attention on the basic principles and limitations of their actions. Future research could analyze additional scenarios to better contribute to the theory of blind spots and to spark the building of a systematic tool that applies the results to real businesses. The tool could be enriched by a more in-depth “what happened and what did not happen” analysis of the scenarios. An evident limitation to this type of research is data availability; many attacks are not publicized because of victims’ reluctance to discuss their specific scenarios.

CONCLUSION

The outcome of this study is that the theory of blind spots in the cybersecurity context can be advanced by making use of a combination of perspectives (“a three-vector approach”). Blind spots exist because there is no focus or there are unknowns, and because people tend to focus on what they think is relevant. These blind spots, illustrated by findings from the study, allow hostile parties to execute cyberattacks. Thus, the responsibility of handling security issues in organizations is not solely for the IT department; rather it is everyone’s responsibility. Organizations and individuals who handle valuable assets in cyberspace will find the present study useful because they will be better able to spot cybersecurity gaps and avoid social and economic costs from successful cyberattacks.

Suggested ways of improving cybersecurity include creating defenses against immediate threats by enhancing mutual situational awareness of threats and vulnerabilities. Moreover, organizations and individuals should develop the ability to swiftly respond to vulnerabilities and prevent network intrusions. In addition, expanding cyber education, research and development efforts, and strategies will likely mitigate malicious activities in cyberspace. A number of organizations, however, are not willing to increase awareness or disclose vulnerabilities because they believe it will create a negative impression for investors and organizational image. In order to enhance cybersecurity return on investment, businesses should provide funding for shorter terms rather than the typical 3-5 years business planning.

KEY TERMS AND DEFINITIONS

Attack Scenario: A cybersecurity incident where an attacker was able to gain illegitimate access to a victim's sensitive information and/or information systems.

Blind Spots: Various biases and preconceived information that affect organizational and human decision making; enabled by unknowns or false focus on what is relevant.

Core Vectors: Economic, technological and psychological perspectives to blind spots; used in combination to obtain a better understanding of what enables cyberattacks.

Cyberattack: A deliberate exploitation of computer systems, technology-dependent enterprises and networks.

Cybersecurity: The organization and collection of resources, processes, and structures used to protect cyberspace from occurrences that misalign de jure from de facto property rights.

Cyber Bullying

C

Jo Ann Oravec

University of Wisconsin – Whitewater, USA

INTRODUCTION

“Cyberbullying” comprises a wide spectrum of behaviors that have negative and often devastating impacts upon their targets (or “victims”). This article is intended to analyze research trends on cyberbullying as well as related concerns involving online harassment, online reputational damage, and cyberstalking. Its focuses are as follows: (1) analyze the creative and innovative conceptual work and research that have emerged on the technological as well as social and ethical aspects of these issues; (2) present insights as to how cyberbullying and reputational damage can best be mitigated, given the technological capabilities and emerging know-how of technical specialists, educators, and organizational consultants; and (3) discuss why cyberbullying is of continuing importance to a broad business, government, non-profit, and educational audience. The article also includes reflections about the moral and personal dimensions of cyberbullying.

Bullying incidents are intricate and frustrating phenomena from whatever contexts they emerge, face-to-face or online. Cyberbullying often involves words and pictures that are considered as protected speech under various national and local laws, often providing cover for those who are attempting to abuse or unsettle a victim (Fraser, Bond-Fraser, Buyting, Korotkov, & Noonan, 2013; Oravec, 2012). The prevalence of cyberbullying is difficult to determine, given the privacy with which many cases dealing with juvenile offences (as well as offences in workplace settings) are handled. In their “Scoping Review on Studies of Cyberbullying Prevalence Among Adolescents,” Brochado, Soares, and Fraga (2016) found the following:

Most of the studies tend to assess cybervictimization experiences. However, even considering the same perspective, the same country, and the same recall period, a high variability in the estimates was observed. As a main conclusion, the way in which the prevalence of cyberbullying is estimated is influenced by methodological research options.

Added to the difficulties in studying cyberbullying is the observation that some individuals who are victimized may not display signs of damage or even choose to respond to the bully. Other individuals may be extremely harmed by comparable words and pictures; some may choose to fight back while others become depressed or even suicidal. Generally, cyberbullying consists of repetitive behavior that has a particular focus on a victim; the bully’s attacks can be shielded from video from others who could possibly intervene. As related in Bonanno and Hymel (2013), “Cyberbullying also takes place on a virtual playground that makes it possible to victimize a peer within the sanctity of one’s own home, at any time of the day or night, in complete anonymity, and with maximal exposure and hence potential embarrassment for the intended target” (p. 646). Kamali (2015) adds an angle relating to the growing assortment of networked devices: “the perpetrator can employ varied means (e.g., cell-phones, texts, blogs, Internet, social media, etc.)” in conducting the bullying (p. 43). Anonymity can give some protection to bullies in shielding them from observation in whole or part of their bullying (Barlett, Gentile, & Chew, 2016). Cyberbullies can also combine anonymous interactions with personally-identifiable ones to make it appear that more than one individual is involved in the attacks, potentially intensifying the negative social impacts of the bullying.

DOI: 10.4018/978-1-5225-2255-3.ch148

Equipping individuals in workplace, community, and educational contexts to be aware of cyberbullying issues may enable them to become more sensitive and empathetic as well as more effective as the front line of defense against these phenomena. It will also help them to mitigate bully-related problems in their organizational and community roles and provide an “early warning system” for the new forms of bullying various technological changes may engender (such as drones and virtual reality). Emerging research efforts may also enhance understanding of cyberbullying as well as empower citizens and organizational participants in their efforts to mitigate it.

BACKGROUND

Public discourse on bullying and mobbing has increased dramatically in the past decade: in the *Journal of Psychohistory*, Dervin (2010) labelled 2010 as “The Year of the Bully” because of the number of shocking incidents involving young people, many of which incorporated some social media component. The classic novel *Lord of the Flies* (Goulding, 1960) has often been mentioned in discourse on youth-related cyberbullying; many of the young people characterized by Goulding had forms of autonomy and power within their environments but did not have the moral guidance to understand fully the consequences of their actions. Cyberbullying attracted public attention in part because of cases such as that of Rutgers University student Tyler Clementi who committed suicide after having some of his sexual activities broadcast via webcam on the Internet (Byers, 2013; Oravec, 2012). “Cyberstalking” has been distinguished as a phenomenon related to and often overlapping with cyberbullying (Adam, 2002; Kamali, 2015); it is more often associated with the conduct of adults than cyberbullying, the latter which has been more often associated with children and adolescents (Carter, 2015). Research from Milosevic (2015) shows that in US mainstream media “overall debate on cyberbullying is narrow, focused on incidents that resulted in suicides, and

subsequent blaming of individuals involved. Such framing can have implications for audience’s support of punitive policies, inability to comprehend complexity of the issue and moral panic around children’s use of technology.” (p. 492).

Computer networking is adding new and complex dimensions to bullying, providing the venue for complex cases of online reputational damage and privacy invasion via social media (Oravec, 2013; Van Royen, Poels, Daelemans, & Vandebosch, 2015). Victims, bullies, and onlookers can often interact in debilitating and confusing patterns in cyberbullying incidents, given their relatively-recent emergence in society and lack of common understandings concerning them. As new forms of cyberbullying emerge, individuals who work online and engage in networked educational and social activity can encounter harassment, belittling, damaging or doctored materials that refer to them, and related harms. Technologies such as digital video, text messaging, and social media can be combined in ways that make victims perceive that they have nowhere to hide and no real legal or social recourse. Victims often lose the ability to contribute their full efforts to their jobs, schoolwork, and social interactions, and sometimes even choose to end their lives.

Cyberbullying can affect people of all gender affiliations; it can also affect individuals of various religious heritages as well as racial and ethnic backgrounds (Cappadocia, Craig, & Pepler, 2013; Stanbrook, 2014). Individuals with disabilities can be targeted as well as become perpetrators themselves (Kowalski *et al.*, 2016). Certain patterns can be found in the way cyberbullying and online reputational damage emerge in the context of various groups and settings, which can help in detecting bullying and mitigating its consequences. For example, some varieties of cyberbullying infuse forms of hate speech (as described in Adam, 2002, Byers, 2013, and Oravec, 2000), integrating themes involving race, gender, religion, or other perceived affiliation; some of this speech, however debilitating to the victim and bystanders, may be protected by the First Amendment (Conn, 2015).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

As individuals engage in increased levels of online activity, the prospects that they will find their online interactions and reputations negatively impacted by others who have somehow targeted them increase as well. Many recent political debates have been affected by cyberbullying, often preventing individuals from engaging fully in citizenship and public forums. For example, Schwartz (2016) describes a number of circumstances in which women's blogs with some political content have been placed under attack with repetitive harassment and abuse. Gender-related and ethnic insults have been common in the online attacks perpetrated in social media as well as email, listservs, and texting venues (Slonje, Smith, & FriséN, 2013); attacks involving sexting (sex-themed technologically-mediated communications) have proliferated as well (Durham, 2016; Oravec, 2012b). In many of these incidents, cyberbullies are enabled to remain anonymous or disguise their identities in ways that only a few of their followers would be able to decipher, increasing the difficulties for law enforcement or administrators to mitigate the situations.

For its victims, cyberbullying has been shown to be linked with subsequent stress and even suicidal ideation (Kowalski et al., 2014). The impact of cyberbullying is often intensified by the ubiquitous nature of computer networking: "For the victim, cyber bullying is pervasive and persistent; once a cyberattack is launched, it is difficult, if not impossible, to eliminate... As a result, the impact of cyber victimization can be (or can be perceived to be) far more negative than that of traditional forms of bullying, and victims may have a much more difficult time coping" (Bonanno & Hymel, p. 686). Cyberbullying has also been shown to affect academic and workplace motiva-

tion, making its control and mitigation a practical as well as moral concern for institutions (Oravec, 2012a; Young-Jones, 2015). Research by Coyne *et al.* (2016) explores "the relationship between experiencing workplace cyberbullying, employee mental strain and job satisfaction," formulating a "disempowerment" approach to understanding its negative effects on the workplace. Kamali (2015) calls for increases in college-directed activity in this arena: "Cyberbullying research on college campuses lacks a unified definition of the concept. Although the states mandated most school districts to develop and enact some sort of policy, the law is silent on the college level cyberbullying" (p. 43).

The study of "serial cyberbullying" (cyberbullying behaviors that are repeated over time by one individual or group) is providing clues as to how bullying operates and who perpetrates it. From an organizational systems perspective, serial bullying is "a cycle that generates when a target is singled out, bullied, and driven from the workplace and regenerates when another target is singled out, bullied, driven from the workplace, and so on" (Lutgen-Sandvik & Tracy, 2012, p. 16). Serial bullies, simply put, can become increasingly proficient in what they do, and their negative impacts on organizations and individuals can be compounded over time as reinforcing network structures grow around them. Repetitive cyberbullying conduct on the part of particular individuals could signal deepseated psychological conditions that can be mitigated through mental health treatment. There are dangers in labeling specific individuals as "serial bullies," however; if these individuals are blocked from subsequent employment and educational opportunities (perhaps unfairly) their life chances can be diminished and opportunities to rehabilitate reduced. However, learning about serial bullying patterns and watching for them can empower human resource specialists and educators to contain repetitive bullying behaviors before they injure more people.

SOLUTIONS AND RECOMMENDATIONS

Cyberbullying prevention and response often involves assistance with the technologies incorporated in cyberbullying for those with low levels of computer literacy. For example, victims often need guidance in documenting cyberbullying and online reputational damage so that their cases can be examined and cyberbullying mitigated. They may need updating on aspects of social media reputation protection and personal privacy guardianship. Unfortunately, many of the organizations that support online platforms (as well as obtain profits from their use) are slow to respond to cyberbullying complaints; a combined initiative among many organizational and online units needs to be maintained for cyberbullying to be mitigated (Stanbrook, 2014). It may certainly be difficult in many workplace contexts for administrators to admit that their organizations have issues with cyberbullying and seek assistance. New research findings about cyberbullying along with various social and artistic initiatives are beginning to generate insights for assistance in helping victims and concerned onlookers. For example, YouTube videos, compelling posters and artwork, and celebrity appearances along with Twitter emojis are being used in public service campaigns to signal that bystanders are becoming aware and involved and cyberbullying is not acceptable behavior (Hayman & Coleman, 2016). Doane, Kelley, and Pearson (2016) describe their research showing that “a brief cyberbullying video is capable of improving, at one-month follow-up, cyberbullying knowledge, cyberbullying perpetration behavior, and TRA constructs known to predict cyberbullying perpetration” (p. 136).

Many well-meaning individuals apparently have an impulse to disseminate widely information about particular cyberbullying cases in public venues. However, publicity about cyberbullying can backfire, despite the intentions of reducing negative outcomes (Pieschl, Kuhlmann, & Porsch, 2015). Publicity can sometimes put the victim’s

own personal history and personal characteristics in a problematic light as people wonder why he or she was targeted. Such publicity may have bad repercussions whether or not the victim’s name was directly mentioned as rumors spread about who was involved.

Surveillance by well-meaning organizational or governmental authorities can play roles in mitigating some aspects of bullying, identifying and documenting potential bullying situations in hopes of containing their damage (Van Royen, *et al.*, 2015). However, with surveillance measures, privacy invasions can emerge as well as the real potential that whatever materials are collected will be misused or taken out-of-context. In turn, Mendola (2015) presents the case that such monitoring has the potential to displace the roles of household controls in a “Big Brother as Parent” scenario. Understanding how surveillance and monitoring can be used to document and frame bullying so as to mitigate its effects will require extensive experimentation in organizational contexts as well as the sharing of best practices.

FUTURE RESEARCH DIRECTIONS

The needs for continuing research on cyberbullying and for the proactive approaches and insights it will engender are considerable. As forms of social media expand, cyberbullying is developing new modes and inflicting new kinds of reputational and emotional devastation. Many participants, onlookers, and victims in cyberbullying and online reputational damage are young adults who may not yet understand the full gravity of harassment, misrepresentation, and related behaviors (Carter, 2015; Oravec, 2013). They are being faced with a difficult and confusing assortment of challenges as they establish their social lives as well as take on moral leadership roles in these contexts. It can be difficult to make a decision as to whether to join with a cyberbully in an online attack (and participate in “mobbing,” defined in the glossary) or have a positive and effective

role as an active intervener or victim supporter. Bullies can be perceived as powerful people, and joining with them may seem at first as a way to enlarge one's own presence and become more powerful in a workplace or educational context (Bussey, Fitzpatrick, & Raman, 2015). Some of the creative tactics against cyberbullying that have been examined by researchers include forms of humor levied by the victims themselves. In a study of Turkish adolescents, Sari (2016) found that "as aggressive humor decreases [on the part of victims], likelihood of cyberbullying perpetration increases. These results indicate that maladaptive humor styles (aggressive humor and self-defeating humor) may successfully address cyberbullying behavior" (p. 555). Research on perceptions of cyberbullying, and how positive associations of them can be eroded (perhaps through humor), may elicit insights as to how to deal with these phenomena.

International comparisons and cross-cultural investigations of cyberbullying will reveal a great deal not just about bullying as a phenomenon but about cultural variations in social psychology (Bayraktar, 2015). For example, in some pioneering longitudinal research on adolescents in Canada, Cappadocia, Craig, and Pepler (2013) found that "Risk factors associated with cyberbullying included higher levels of antisocial behaviors and fewer prosocial peer influences. Risk factors associated with cybervictimization included being in the transition year for high school, as well as higher levels of traditional victimization and depression." (p. 171). Scales such as the Revised Cyberbullying Inventory (RCBI) can be used to elicit results that can provide some sort baselines for what is happening with cyberbullying phenomena over time and across cultures. Using the RCBI in a study of British adolescents, Brewer and Kerslake (2015) found the following:

Empathy was a significant individual predictor of cyberbullying perpetration, such that as empathy decreases, likelihood of cyberbullying perpetration increases. These findings indicate

that self-esteem and empathy oriented interventions may successfully address cyberbullying behavior. (p. 255)

C

Cultural and psychological insights on cyberbullying may be productively combined with cybercounseling approaches to design workplace and educational interventions (Mishna, Bogo, & Sawyer, 2015) which can be implemented and evaluated in real-life contexts.

CONCLUSION

Decades ago, many of the future projections for the uses of computer networks seemed to present bright and optimistic portraits (Natale & Balbi, 2014; Oravec, 1996); computing technology innovations would be used primarily to inform, share, and befriend others. However, many dystopian scenarios are emerging worldwide of individuals who are afraid to participate in online interaction because of the negative impact it can have on their lives, scenarios that are echoed in the real-life experiences of many students and employees (Adam, 2002; Byers, 2013). Cyberbullying research has indeed documented specific cases of cyberbullying and elicited trends, but the deeper and more difficult moral questions remain of why so many individuals use computer technology in ways that disempower and wound people. These phenomena are apparently taking on new forms as computing technologies expand their reach societally (in terms of their national and international permeation) and personally (in terms of how we live our everyday lives).

In conclusion, managers, administrators, educators, and concerned citizens need to consider how to deal with generations of individuals (from young people to older adults) who have suffered from painful and reputation-damaging personal attacks online. Workplaces have also been sites for extended and sophisticated cyberbullying efforts, which have served to decrease levels of organizational morale as well as productivity. Many

students have become acquainted with cyberbullying in school contexts, in some cases learning how to be participants and in others how it feels to be a victim; educational institutions may be able to foster more positive and healthy behaviors as well. Inclusive excellence cannot be obtained if individuals live in fear. People cannot be expected to learn effectively or produce their best work if they regularly need to deal with cyberbullies or are themselves inappropriately or unfairly being construed in that light. Continuing research and public discourse on these matters is necessary for society to benefit fully from computer technology and social media.

KEY TERMS AND DEFINITIONS

Bystanders: Individuals who have access to information about current or potential bullying or harassment incidents, whether or not they choose to respond. In online contexts, information that is received by bystanders may be fragmented and highly confusing.

Cyberstalking: Repetitive and personally invasive surveillance and monitoring of a target or victim, often with unsettling forms of unwanted contact. Cyberstalking is often associated with adult behaviors more than those of children or young adults (Kamali, 2015).

Mobbing: Group member cooperation and collaboration in bullying. From the victim's perspective, mobbing compounds the negative power of abusive behavior with the sense of exclusion from the group, producing a form of "psychological terror." From the mobbers' perspectives, mobbing may make the participants feel less guilty about their behaviors since their peers and comrades are also engaging (Leymann, 1990).

Online Reputational Damage: Injury to the online profiles and compiled reputational information about an individual. This injury can be conducted through such means as doctoring photographs and manipulating online information in a negative way (Oravec, 2013).

Serial Cyberbullying: Individuals who engage in bullying who have chosen more than one target or victim, either simultaneously or sequentially. Serial bullying has been widely documented

in non-computer assisted forms of bullying as well as online varieties. It has also been observed among children and young people (Carter, 2015).

Victim: The intended target of the online abuse. The term “victim” can it itself have negative implications for those for whom it is applied, with connotations of “opportunistic victimhood” and assumptions that the target somehow is benefiting from the abuse or did something to attract it intentionally.

INTRODUCTION

The Internet, a technology that cuts across geographical borders and overcomes the challenges of time is considered the most influential technological development in the 21st Century (Dholakia & Kshetri 2004). It has been described as the modern Pandora's Box that has opened a new cyberspace of threats to unwary users (Ktoridou, Eteokleous & Zachariadou 2012). Given the broad use and the rapid sophistication of the cyber technology over the years, the Internet is gradually replacing conventional (traditional) media of communication and becoming not only a new means communication but also a new means of interaction and socialization for millions of users nowadays (Ktoridou et al. 2012).

Rapid innovative advancements in the cyber technology and cyber-related technologies have exceptionally augmented the capacity and categories of users over the decades. According to Dholakia and Kshetri (2004), the Internet took only three years to reach 50 million users around the world compared to the 13 years taken by the radio and 38 years by the television. Approximately 2.9 billion people all over the world have access to the Internet, representing around 41% of the world population, and this number continues to increase (Kenda 2014).

The cyberspace is rapidly becoming a medium for people to meet their everyday needs like searching for information, communicating and entertainment (University of Southern California, [USC] Annenberg School Center for the Digital Future [ASCDF], 2008). The cyberspace has certainly provided enormous benefits and advantages to the people (Lenhart, Madden & Hitlin 2005). A meta-analysis study by Guan and Subrahmanyam (2009) has found that the cyber technology is a useful tool for promoting youth cognitive, social and physical development. In addition, scholars have emphasised the great utility of the Internet in successfully raising awareness regarding health issues, enhancing social relationships, maintaining community links among the young people and numerous other benefits (Barak & Sadovsky 2008; Subrahmanyam & Greenfield 2008; Flicker, Maley, Ridgley, Biscope, Lambardo & Skinner 2008).

Despite the positive effects of the cyberspace on users, the technology exerts some negative influences as well (e.g., cyberbullying), especially on children and the youth (Livingstone, 2012). Nowadays, Malaysian children and adolescents are increasingly using cyber technology at younger ages, with diverse devices and technologies (Balakrishnan 2015). In recent years however, there has been growing concern by the public, schools and parents about children and youth involvement

in online risk behaviors such as cyberbullying and harassment (Finkelhor, Mitchell & Wolak 2000; Wolak, Mitchell & Finkelhor 2006). Many Malaysian youth and children have been exposed on daily basis to numerous Internet risks and harms (Balakrishnan 2015).

Given the ease of access and use of Internet technologies, even children learn how to use it; some children even go to the extent of protecting their online privacy from the prowling eyes of their parents (Yusuf, Osman, Hassan & Teimoury 2014). With just a click on the keyboard/keypad, children can access almost anything, including any kind of video, article and image they desire, including what they might stumble across accidentally (Balakrishnan 2015; Ktoridou et al. 2012), which often leads to incidences of cyberbullying, where children are being bullied by others while online (Yusuf et al. 2014).

This suggests that cyberbullying has been posing growing concern, especially for the online safety of the youth and children. Furthermore, there have been significant and rapid changes in children and youth's online activities in the last one decade in the country (Balakrishnan 2015; Yusuf et al. 2014). Evidently, there has been remarkable increase in the use of smartphones by the youngsters coupled with their migration from social activity to social networking sites across societies in the world (Jones, Mitchell & Finkelhor 2012) and in Malaysia (Abu Bakar 2013; Balakrishnan 2015).

Abu Bakar (2013) has empirically supported the issue that cyberbullying is a silent epidemic in the Malaysian society. The scholar indicated that online harassment and sexually based cyberbullying are the most common forms of cyberbullying in the country. Over the recent years, many incidents of cyberbullying had occurred on the Internet, which led to cases such as homicide, sexual assault, humiliation and assault. Cyberbullying incidents are increasing every in the country and becoming a potent threat to children, parents

and other stakeholders (Neging, Musa, R. & Abdul Wahab 2013).

Norton Family Report (NOFR) (2010) indicates that the rising popularity of the new media and the increasing amount of time children spend online pose great challenges to parents and or guardians who want to protect their children from the threats and harms of the cyberspace. Hence, this study was prompted by the urge to understand the prevalence of cyberbullying in Malaysia by determining the level of the phenomenon among children. One major area that this chapter has contributed to is the development of a scale suitable for measuring cyberbullying in Malaysian society. Given that previous research focuses on qualitative approach such as face-to-face and telephone interviews, there has been a dearth of quantitative scale to measure cyberbullying, particularly on sexually based cyberbullying and online harassment dimensions. Therefore, this study adopted a quantitative approach.

BACKGROUND

Cyberbullying in Malaysia

According to an Interpol statistics, online harassment is growing rampantly all around the world, and Malaysia is no exception. It has been reported that one in every five children online becomes the target of cyber predators and 30% of female children have been sexually harassed in a chat room (Azizan 2012).

The cyber security unit of Malaysia have conducted a survey on the effect of cyber threats on children and adolescents and found that about 60% of the cases reported to them were about cyberbullying on social networking sites such as Facebook and MySpace (Nik Anis, Abdul Rahim, & Lim 2012). Despite the limited number of literature on cyberbullying among Malaysian youngsters, a study conducted by Balakrishnan (2015) found

that cyberbullying does occur among Malaysian youth. However, Balakrishnan (2015) suggests that occurrence of the phenomenon among the respondents of the study (youth aged 17 to 30 years old) was not as prevalent as it is among children and teenagers, and that social networking sites are the most likely domains where cyberbullying incidences take place.

In addition, there are many none-empirical evidences of cyberbullying occurrences in Malaysia. In 2010, not less than 60 cases of cyberbullying were reported to the cyber security unit of Malaysia in 2007 (McKenna 2010). Surprisingly however, the number of reported cases rose to 5,181 in 2009 and 11,930 in 2010 (Cyber Security Malaysia Report [CSMR] 2011). Furthermore, various media reports in Malaysia have suggested that cyberbullying is prevalent among children and the youth. However, much of it could have been under-reported because most people are unaware that it has become a serious issue (Eek 2009).

According to Roberts and Samani (2013), the McAfee and ABA (Anti Bullying Alliance) surveys have found that cyberbullying is one of the critical online phenomena that children and youth face nowadays. Nik Anis et al. (2012) also reported that besides cyberbullying, the main online threats to Malaysian children while online are cyber-grooming, identity theft and child pornography.

The findings of a national survey conducted by Malaysian Cyber Security in 2011 indicates that more than 90% of children aged 5 to 18 in Malaysia may have been exposed to cyber threat. Findings of NOFR (2010) survey indicate that due to their excessive use of the Internet, 87% of 553 Malaysian children surveyed indicated having been bullied by cyber predators. Furthermore, the results of a national survey of school-going children in Malaysia shows that almost 30% of the children indicated that they have been bullied while online. However, only 13% of them admitted being bullied almost every day on the Internet (CSMR 2014, 2013).

LITERATURE REVIEW

Children in Digital Age

The literature stresses that social networking sites like Facebook and Twitter, search engines such as Google, MSN (Microsoft Network), Yahoo and WIKIs are an established part of Internet users' daily life events (Eteokleous & Pavlou 2010). Adolescents mainly under the age of 18 are the highest users of this digital realm. These adolescents are commonly referred to as Digital Learners (Murugesan 2009), Net Generation (Myers, McCaw & Hemphill 2011), Millennial Teens or Generation Y (Negin et al. 2013) and Digital Natives (Prensky 2001) since they were born and growing up in the Information Technology (IT) age (Ktoridou et. al 2012). This group of users is the main consumer of the Internet since the first official outbreaks of the Internet in the mid-1990s (Ward 2011).

In contrast, children that were born or growing up during the time of Internet technological evolution are classified as the digital immigrants (Prensky 2001). These users are using the cyber technology and associated technologies based on their needs for survival by adjusting to the environments as part of their daily lives (Ktoridou et al. 2012). Since new generations are the frequent users of the Internet, it follows that they are more aware of the use, the tools and the features of the Internet than the older generations (Davidson & Martellozzo 2008). Consistent with the facts, a research conducted in 21 European countries has showed that 75% of children in European countries are using the Internet and the rate continues to grow everyday (Livingstone & Haddon 2009).

Adolescents and youths are the most fervent users of the Internet, who have embraced cyber technology and digital media as a lifestyle for communicating, making connections, interacting and social networking (Ktoridou et al. 2012). The researchers further indicated that the Internet has the ability to communicate with people without

limits regardless of the languages, cultural and geographical diversity, simply by using the social network (e.g. Facebook and Twitter), chat rooms (e.g. Skype and Yahoo Messengers) and various other forums. Through all the convenient tools for socializing, people from all over the world with various background and cultures can connect easily and quickly. According to Eteokleous (2011), this technology enabled children to understand, to discover new things, and to express their feelings without boundaries and limitations. In addition, a survey by the Malaysian Communication and Multimedia Commission (MCMC 2014) reports that almost 65% of Malaysian population has access to the Internet out of which 17% are children and adolescents aged 7 to 19 years old.

A recent research conducted in the United Kingdom (UK) reported that one of the main predictors of risks and harm among children as young as nine years old is indulging in risky online behaviors (Livingstone & Gorzig 2014). Furthermore, nearly 11% and 13% of adolescents within the age range of 9 to 16 years old in the UK have already seen an online pornography and seen or received hateful messages respectively (Livingstone 2012).

A study found that 95% of young adults aged 18 to 29 have easy access almost anywhere to the Internet via high-speed broadband and smartphones (Pew Internet and American Life Project [PI&ALP] 2013; Zickhur & Smith 2013). According to them, this scenario has led us to the disturbing reality of the Internet norms these days that not all of the access to the Internet is safe, particularly for adolescents and children.

A number of research surveys have suggested that majority of children aged between 12 and 14 years use the Internet intensively, spending about 15 to 20 hours per week communicating, passing pastime and entertaining themselves (Livingstone, Bober & Helsper 2005; USC ASCDF 2008, 2005; Van den Eijnden, Spijkerman, Vermulst, Van Rooij & Engels 2010; World Internet Project [WIP] 2013; Zamaria & Fletcher 2007).

The Concept of Bullying

According to Carter (2011), resolving conflicts amongst adolescence is a normal part of their maturation process, and usually will be disclosed in bullying behaviors, with bullies threatening other students who may be perceived as vulnerable or weak. This kind of behavior is identified as either traditional bullying or cyberbullying. Since bullying behaviors occurred during the process of growing up, Banks (1997) has identified that bullying might increase during elementary school, will be at uttermost frequency during middle school years and will be decreasing in high school.

In order to comprehend the phenomenon called cyberbullying, it is important to understand the concepts of traditional bullying better. Olweus (2002) formulated a systematic terminology of bullying. The researcher defines victimization or bullying as a situation when a student is exposed repeatedly and over time to negative actions on the part of one or more students. The researcher further explains that negative action is when someone intentionally inflicts, or attempts to inflict, injury or discomfort upon another (Olweus 2002). Smith, Mahdavi, Carvalho, Fisher and Russell (2008) comprehensively but concisely defined bullying as the act of verbal, physical, relational and indirectly bullying often referred to in the scholarly literature, media and Internet as traditional bullying.

This early concept of bullying has been used for decades by researchers to identify the bullying behaviors among children and adolescents. Nansel, Overpeck, Pilla, Simons-Morton and Scheidt (2001) reinforced the term bullying with an additional important characteristic, the imbalance of power that exists in which the bully or bullies are considered more powerful by attacking a victim who is less powerful. Based on this consideration, experts of bullying behaviors have shared same views that bullying is a major concern in the society as it leads to negative outcomes for the victims' physical and psychological well-being

(Noordahl, Poole, Stanton, Walden & Beran 2008; Smokowski & Kopasz 2005). Many victims of bullying can vividly recall being harassed during childhood, especially victims who cannot properly defend himself or herself because of the difference in strength and size (Hinduja & Patchin 2009). According to a dissertation by Carter (2011), bullying problems often go undetected and unreported because many people view bullying as a normal part of life especially in middle and high school, as most people believe that it is normal for children to fight and they have to learn how to protect themselves the hard way.

The Concept of Cyberbullying

Cyberbullying has been defined as the act of willfully using electronic and/or cyber technologies to deliberately and repeatedly harass or threaten someone by sending or posting cruel text and/or graphic messages (Abu Bakar 2013; Berson, Berson & Ferron 2002; Finkelhor, Mitchell & Wolak 2001, 2000; Hinduja & Patchin 2009). Smith et al. (2008) defined cyberbullying as an aggressive, intentional act carried out by a group or individuals, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself.

Researchers argued that cyberbullying could occur anywhere and at any time, this empowers bullies much more than traditional bullying does because more targets could be harassed through cyberbullying with less effort on the part of the bully (Garinger 2008). This indicates that the time taken by a cyberbully to harass someone is now limited to the speed of a click of the mouse and the spread of threats is no longer limited to the cyberbully and cybervictim (Mitchell 2011). Meanwhile, surveys have reported that in Malaysia, majority of children spend as many as 19 hours per week on average using the Internet (NOFR 2010). According to the report, the rising popularity of the new media and the increasing amount of time children spend online pose great challenges

to parents and or guardians who want to protect their children from the threats and harms of the cyberspace. A new form of bullying commonly referred to as cyberbullying has become a new growing problem on the Internet in nowadays (Carter 2011). Smith et al. (2008) defined cyberbullying as an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself.

Generally, cyberbullying is not that much different from traditional bullying, even though it has changed overtime through the advancement of technology. Bullies nowadays have moved from the school grounds to behind-the-cellular-phone or computer screen (Hinduja & Patchin 2010). According to the researchers, the availability and use of technology by the young people is on the rise and so is the ability to become cyberbullies or cyber predators.

Similarly, Sharif (2008) indicate that rapid advancement of Internet and cellular technologies has opened up a new and infinite space that young people can explore with fewer restrictions, as the digital media offers convenient opportunities to humiliate, bully, or harass someone online. A new variation of bullying has transformed from the physical to the virtual, it becomes insidious when cyberbullying grows into a form of psychological cruelty (Sharif & Hoff 2007) and in some cases will end up with the loss of lives (Abu Bakar 2013).

Types of Cyberbullying

Cyberbullying could take place every hour, every day, throughout the week (24/7) from anywhere (Willard 2007). According to the researcher, cyberbullying can take place through the information technology that (IT) students access every day, including cell phones, text messages, e-mail, instant messaging, social networks, pictures and video clips. Garinger (2008) suggests that since cyberbullying can occur anywhere and at any time, this empowers bullies to a greater degree

compared to traditional bullying. More targets can be harassed through cyberbullying with less effort on the part of the bully (Garinger 2008; Willard 2007). This implies that the time a cyberbully uses to perpetrate an attack is now limited to the speed of a mouse click and the spread of threatening attack is no longer limited to the bully and target (Mitchell 2011). There are eight distinct forms of cyberbullying, namely flaming, harassment, denigration, impersonation, outing and trickery, exclusion, cyberstalking and cyberthreats (Willard 2007). Table 1 contains eight distinct forms of online harassment, which Willard (2007) has outlined.

Trolling, happy slapping and sexually based bullying are other forms of cyberbullying (Ybarra & Mitchell 2004). Online harassment is defined as “threats or other offensive behaviors targeted directly at youth through new technology channels (e.g., Internet, text messaging) or posted online about youth for others to see” (Jones et al. 2012, p. 54). According to Willard (2007) online harassment is the act of aggressive behaviors, including insulting someone online, making nasty or threatening remarks through e-mail or instant messages, spreading unwanted images or video clips of someone and creating offensive pictures or images and posting them online in order to humiliate somebody.

Sexually based cyberbullying is also a common form of cyberbullying (Mitchell & Jones 2011) and it involves sexual solicitations and unwanted exposure to sexual materials such as pornographic pictures, pornographic video clips and sexually suggesting gestures posted online or done with the aim of arousing sexual feelings in the targeted persons or making them feel sexually abused. According to Abu Bakar (2013), online harassment and sexually based cyberbullying are the two most prevalent forms of cyberbullying in Malaysia.

According to Mitchell and Jones (2011), sexual solicitations and exposure to unwanted sexual materials are a wide range of negative cyber experiences affecting children. The researchers defined sexual based cyberbullying as sexual

Table 1. Categories of cyberbullying

Type of Bullying	Description
Flaming	• Short lived argument between protagonists • Extended, heated argument leading to threats of violence • Questionable credibility of threats
Harassment	• Repeated ongoing assault • Usually one sided • Can have multiple protagonists harassing a target • Some protagonists may not even know the target • Could be criminal especially if involving hate or bias • Target is direct recipient of material
Denigration	• Harmful, untrue, or cruel speech about a target • Posted online and/or circulated via email, texting, instant messenger • Target is not direct recipient • Included public postings and sending of digital images (which may have been digitally altered) • May include defamation or invasion of privacy
Impersonation	• Falsely identifying as the target • Posting or sending material that shows the target in a bad light or interferes with target's relationships and friendships • Often a means of the protagonist getting the target in trouble with authorities
Outing and Trickery	• Posting or otherwise circulating images and other personal communications that are embarrassing to the target • Target is not direct recipient of the attack • Images are often sexually suggestive and verge on sexual harassment
Exclusion	• Deliberate exclusion of the target from communications to which he or she was previously privy to • Often occurs when the protagonist convinces multiple people to defriend [unfriend] the target
Cyberstalking	• Including the repeated harassment threats of harm • Can be intimidating, offensive, or involve extortion • Protagonist often lulls target into sense of false security before slowly escalating harassment

Source: Willard (2007).

solicitation, which involves an urge to participate in a sexual activity willingly or unwillingly, made by someone online. Sexually based cyberbullying also involves exposure to sexual materials such

as pictures of naked people or people having sex while surfing the web, doing online search, opening e-mails or instant messages, or opening links in e-mails or instant messages (Abu Bakar 2013; Mitchell & Jones 2011).

Patterns of Cyberbullying

Furthermore, through commonly used channels such as blogs, chat rooms, file-sharing applications, social networking sites and mobile phone messages, children and young people can be threatened, excluded from activities or humiliated by having misleading messages or photos about them posted online (Eek 2009). According to an online survey, these aggressions among youngsters are mostly channeled through social networking sites; 54% of 10,000 participants aged 12 to 17 have reported having experienced cyberbullying on Facebook (Roberts & Samani 2013).

Impact of Cyberbullying

Over the past decade, cyberbullying has become more dangerous and more virulent form of bullying to the extent that insidious forms of victimization now lurk in online community resulting from cyberbullying (Raskauskas & Stoltz 2007). Cyberbullying is one of the biggest threats confronted by young people and it has become a common phenomenon among youth nowadays (Abu Bakar 2013). The effect of cyberbullying is more traumatic than traditional bullying since victims can be bullied 24 hours and 7 days a week from anywhere as long as there is a working Internet connection (Willard 2007). Besides the unlimited accessibility to the victims, cyberbullying also causes psychological abuse to the victims including teasing, intimidation and exclusion in ways that do not exist in traditional bullying (Raskauskas & Stoltz 2007).

Cyberbullies usually seek to exert dominance and power over the victim and inflict psychological torture such as the feeling of low self-esteem, loneliness, poor mental health, peer rejection,

depression, isolation and hopelessness in their victims (Hinduja & Patchin 2010; Pranjic & Bajraktarevic 2010). According to the Center for Disease Control and Prevention [CDC&P] (2010), these negative feelings could even influence children to consider committing a suicide.

Between 2003 and 2012, some 34 cases involving cyberbullicides (committing suicide because of being cyberbullied) were reported, while in 2013 alone, seven cases were reported (Abu Bakar 2013). In 2007, suicide was found to be the third leading cause of death among younger citizens of USA aged 15 to 24 years old (American Foundation for Suicide Prevention [AFSP] 2007). Generally, however, research directly linking cyberbullying to suicide is quite limited (Brunstein-Klomek, Sourander & Gould 2010; Pranjic & Bajraktarevic 2010).

Material and Methods

Cyberbullying dimensions were constructed based on the conceptual framework of this study and a review of extant literature. As mentioned earlier, there are many forms of cyberbullying. However, this study focuses on sexually based cyberbullying and online harassment. For the measurement of sexually based cyberbullying dimension, a scale developed by Mitchell and Jones (2011) and Livingstone et al. (2011) was adopted. While, for the measurement of online harassment dimension (which is related to acts of aggressive behavior online), a scale developed by Livingstone et al. (2011) was adopted with modifications. The original survey scale consists of four items on risk and harm towards child's safety (i.e. bullying, pornography, sexting and meeting strangers online).

This study designed a scale consisting of an inventory of 10 items measured using five-point Likert scale was developed. Two constructs (online harassment and sexually based cyberbullying) were involved, each measured by five items. However, to ensure that the scale is valid in Malaysian context and to help the respondents

(children) understand the questions better, several modifications were made. Respondents were asked to answer the questions based on a 5-point Likert scale: “1 never, 2 seldom, 3 sometimes, 4 often and 5 very often. As part of the modifications, some words/phrases in the original scale that sound sensitive in Malaysian context were changed based on the advised given by Ministry of Education in the country. For example, having sex was replaced with obscene acts and pictures of naked persons was replaced with inappropriate materials in the modified scale. Table 2 shows the complete original and modified items in the scale.

Given that Malay language is the primary national language and English language is treated as a secondary national language, to ensure that the respondents understood the questions very well, the survey instrument was designed in both languages.

Stratified random sampling perspective was adopted to select 378 pupils aged 9 to 16 years old from eight primary schools in Selangor State.

Only children that had experienced cyberbullying in the past 12 months were selected. Paired, coded survey forms were administered to the young participants in order to avoid non-response bias respondents (see Singer 2006).

The respondents were collected into small groups during class hours and were administered with the questionnaire, which they completed under the supervision of their researchers. Either of the children’s parents was also selected to participate as a respondent. A few trained enumerators were employed who read out the questionnaire aloud for the younger respondents aged 9 to 11 years old. Although the average time to complete the questionnaire was about 15 minutes, it took the younger respondents about 30 minutes or more to complete. The questionnaires were retrieved on the same day after the pupils had finished completing them; 61 forms from the children and 49 forms from their parents were recovered.

Factor analysis was used, and the questionnaire was reduced to 378 after data cleansing. Construct

Table 2. Original and adapted cyberbullying scales

Original Items (Qualitative Approach)	Adapted Items (Quantitative Approach)	Dimension and Source
Has anyone ever sent you nude or nearly nude photos or videos of kids who were under the age of 18 that others took?	I have been sent inappropriate messages on the Internet	Sexually-based Cyberbullying (YISS 1, 2 and 3) by Mitchell and Jones (2011)
Did you ever open a message or a link that showed actual people/naked people/people having sex that you did not want?	I have seen inappropriate materials posted where other people could see it on the Internet.	
Did you ever find yourself in a website that showed pictures of naked people/having sex when you did not want to be in it?	I have seen other people perform obscene acts.	
Did anyone on the Internet ask you for sexual information? Like, what your body looks like or sexual things you have done.	I have been asked on the Internet for a photo or video showing my private parts.	
Did anyone on the Internet ever try to get you to talk online about sex when you did not want?	I have been asked to talk about nasty acts with someone on the Internet.	
Nasty or hurtful messages were sent to me.	I have received nasty or hurtful messages.	Online Harassment (EUKidsonline) by Livingstone et al. (2011)
Nasty or hurtful messages about me were passed around or posted where others could see.	Nasty or hurtful messages about me were posted or passed around online where others could see.	
Other nasty or hurtful things on the Internet.	I have received other nasty or hurtful things on the Internet.	
I was threatened on the Internet.	No changes made	
I was left out or excluded from a group or activity on the Internet.	No changes made	

reliability test was then run. The Cronbach alpha coefficient value (α) for the construct for pre-test was $\alpha = .830$ ($n = 63$)¹ while for actual data collection was $\alpha = .75$ ($n = 375$). This indicates that the scale was very reliable (see Salkind 2008). Furthermore, a committee of experts reviewed the cyberbullying items and validated it. Approval from Malaysian ministry of education and the Selangor State department of education was also obtained. Similarly, consent was obtained from authors whose works were adopted in this study.

RESULTS

Respondent's Demographic Profile: Children

The respondents' demographic information shows female respondents were almost twice as many as male respondents. That is, the disparity between the proportion of the male (35.2%) and female (64.8%) pupils was very wide. The respondents were divided into two age groups for data analysis convenience. The first group was the younger group, comprising 155 pupils aged between 9 and 11 years old. The second group was the teenage group, comprising 232 respondents aged between 13 and 16 years old, with exception of 15 year-old age group whose members were sitting a compulsory examination. Generally, the respondents were aged between 9 and 16 years old ($M=12.51$), with more than two-thirds of them (60.1%) aged between 13 and 14 years old. Many (57.6%) of them lived in urban areas (see Table 3).

Respondents' Demographic Profile: Parents

Male parents are slightly fewer than the female parents were, fathers, 44.8% and mothers, 55.2%. Many (56.8%) of them were aged between 42 and 53 years old. Quite many (40.5%) of them were aged 30 to 41 years old, with only few of them

Table 3. Descriptive statistic of respondents' demographic profile (n=375)

Variables	Frequency	Percentage

(2.4% and .3%) were aged between 54 to 65 years old and 18 to 29 years old respectively ($M=43$, $SD=5.43$) (see Table 4).

Majority of the parents were Malay (73%) by ethnic identity and Muslims (74%) by religious identity. The parents' educational qualification data indicates that 26.7% of them were Bachelor degree holders, 25.3% held SPM², 20.5% held Diploma and less than 10%. Only very few (1.3%, $n=5$) of them had never been to any school. The monthly disposable income data shows that majority very many (60.8%) of the parents earned RM3,000³ or less.

Prevalence of Cyberbullying Incidences Among the Children

C

This study discovers that the gaps between the children's responses on 'never experienced', 'sometimes experienced' and 'often experienced' were wide. Unpredictably, nearly all (94.1%) of the respondents indicated never having experienced any online threat ($M=1.11$, $SD=.22$). Extremely few of them experienced any cyberbullying as indicated by the overall mean value ($M=1.15$, $SD=.33$) (see Table 5).

Level of Cyberbullying Incidences Among the Children

Overview

Level of cyberbullying refers to the degree of prevalence of the occurrence of cyberbullying incidences. The level is measured using 'Low', 'Moderate' and 'High' scales (see Sharma, Mukherjee, Kumar & Dillon 2005). The scores of the level are derived based on the cut-off mark method, by subtracting the minimum scores from the maximum scores of the responses and are then divided into three levels (see Sa'ari, Wong & Roslan 2005). For example, the overall mean score of cyberbullying is $M=1.15$, $SD=.33$. The level of cyberbullying (see Table 6) is determined marking off this mean score in the level scale, which was designed based on the method mentioned above.

The overall mean value of cyberbullying scale is $M=1.15$, $SD=.33$ (refer to Table 5). Based on the results in Table 6, the level of cyberbullying among Malaysian children is moderate.

DISCUSSION

The results reveal that extremely few (3.9%) of the respondents have ever been threatened online. In addition, only quite a few of them experienced any

Table 5. Percentage of frequency, mean and standard deviation of cyberbullying (n=375)

Items	Likert Scale (% of Frequency)					Mean	SD
	1	2	3	4	5		
I have seen an inappropriate materials posted where other people could see it on the Internet.	79.2	17.7	1.1	1.0	1.0	1.24	.44

Overall score						1.15	.33

Note: Likert scale: 1 never, 2 seldom, 3 sometimes, 4 often and 5 very often; M: Mean, SD: Standard Deviation

Table 6. Level of cyberbullying (n=375)

Level	Percentage	Overall Mean Value of the Scale	
		Mean	SD
Low (1.00 – 1.04)	10.0	1.15	.33
Moderate (1.05 – 1.23)	80.0		
High (1.24 – 5.00)	10.0		

Note: SD: Standard Deviation.

form of sexually based cyberbullying as follows. Only a few (20.8%) of them had seen inappropriate materials at least once posted online, quite few (16.0%) of them had ever seen inappropriate materials posted online and only extremely few (14.5%) of them had seen people commit obscene acts online.

Similarly, quite few of the children have ever been harassed online as indicated by these percentages. Only 11.1% of them have ever suffered the humiliation of being expelled from an online group; and others have ever ridiculed only 10.1% of them through posting their pictures online where others could see them. Only 4.2% of them have ever been asked by someone to share the picture or video of their private parts online; and only 3.0%

of them have ever been cornered by someone to talk about nasty things online. The results generally suggest that majority of the children have only mildly (moderately) experienced at least one form of cyberbullying or another at some point in time within the past one year. However, majority of them never experienced or got involved in any form of cyberbullying or its related incidence with any serious degree.

This outcome further suggests that either many of the children have been involved in cyberbullying incidences (as cybervictims or cyberbullies) more than once in the past one year but have been unaware of what it constitutes, or (fortunately) have never been exposed to any cyberbullying act. This finding is consistent with the findings of a

survey conducted by the Malaysian cyber security in collaboration with a mobile telecommunication company in 2013 (CSMR 2013).

Therefore, putting the frequency distributions into perspective, this chapter suggests that mild cyberbullying incidences actually occur among Malaysian children but that majority of them have been unaware of what it constitutes. The children may have been passing it for a normal part of online social interaction, especially if the cyberbullying incidences occur on social network sites (see Balakrishnan 2015; Lenhart, Madden, Smith, Purcell, Zickhur & Rainie 2011).

Online harassment has been the most prevalent type of cyberbullying incidence in the country. Wolak et al. (2006) supports this finding empirically. Similarly, Bernama (2012) supported this finding. Although mildly, incidences of online harassment are increasingly becoming prevalent nowadays because children and youth have unprecedented access to information and communication technologies such as smartphones, tablets and Internet connection (Abu Bakar 2013; Hinduja & Patchin 2009).

FUTURE RESEARCH DIRECTIONS

This chapter identifies the absence of a standard cyberbullying measurement scale suitable for Malaysian context as a challenge and limitation. The scale adopted in this study, which were used in the United States (see Mitchell & Jones 2011) and various European countries (see Livingstone et al. 2012) have been suitably reliable in those contexts, and have produced predictable results. However, the findings of the current study have rather been unpredicted.

This study is only limited to quantitative approach. Hence, this chapter recommends that future research should focus on qualitative approach in Malaysian context. Qualitative data can be used to conduct an in-depth observation of the causal relationships between cyberbullying other social factors such as demographics or parent-child

relationships. Therefore, future research should attempt to explore the relationships between cyberbullying and demographic characteristics such as gender and age, as well as parental attachments. It is expected that this approach can generate new and reliable cyberbullying scale for Malaysian society. Qualitative methodologies studies such as in-depth interviews, focus group discussion, content analysis and audio recordings can provide valuable insights and facilitate a clearer interpretation of factors affecting cyberbullying among Malaysian children (see Festl & Quandt 2013).

This study focuses on cyber victim (being a victim of cyberbullying) dimension only because most Malaysian children and adolescents that have got involved in cyberbullying acts have been victims rather than bullies (Balakrishnan 2015). However, to get a comprehensive understanding of cyberbullying, future research should investigate the effect of cyberbullying on other parties involved in the behavior, namely the bully, the bully-victim and the by-stander (audience) (see Camacho, Hassanein & Head 2014).

CONCLUSION

This study has discovered that generally, the level of cyberbullying among Malaysian children is moderate. Specifically, however, incidences of online harassment occur more often than those of sexually based cyberbullying do. The findings also reveal that majority of the children have experienced a cyberbullying incidence at least once in a year, which gives the hints that with time, cyberbullying could become a menace to the innocent Malaysian child online (see Balakrishnan 2015). Nonetheless, the threat posed by cyberbullying to the children has been moderate, which implies that the online safety of majority of Malaysian children is guaranteed at present. Therefore, this study concludes that mild cyberbullying incidences actually do occur among Malaysian children, however, most of the children have been unaware of what it portends.

However, parents are advised to control their children's access to and usage of technologies as well as monitor their behavior. Parents should report any cyberbullying incidence case to the Police. The Malaysian cyber security should maintain the annual cyberbullying survey. Children should be pedagogically instructed about online risks and safety. Therefore, the Ministry of Education is advised to introduce subjects on cyber safety and threats in elementary and high schools. Lastly, the Malaysian Communication and Multimedia Commission (MCMC) should organize seminars on online safety and threats periodically to enlighten parents, adolescents and young adults about the dangers lurking in the online milieu and teach them ways of avoiding or managing involvement in cyberbullying.

KEY TERMS AND DEFINITIONS

Adolescents: This term refers to growing up children, aged between 13 and 17 years old.

Children: This is an umbrella term that refers to pupils (boys and girls), usually aged between six and 16 years old.

Cyber Predator: This term refers to online bullies, i.e., individuals who bully cyber victims.

Cyber Victim: This term refers to a boy or a girl who has been affected by cyberbullying.

Cyberbullying: This refers to intentional inflicting of psychological torture and hurling of abusive words online (in text, graphics or audio-visual formats) by a person (adult or minor) targeted at a minor or a group of minors using the Internet aimed at scaring them.

Cyberspace: This term refers to the online environment where cyberbullying occurs, i.e., the Internet.

Internet: This term refers to the global, wireless networked digital technology service that connects one computer device to another and facilitates sharing of information and effective communication between users smoothly and promptly.

Online: This term is often used as a synonym of Internet. It also refers to an activity performed on Internet-enabled platform or application such as the World Wide Web (www).

Online Risk Behavior: This refers to a particular social behavior that portends threats exhibited by persons (adult or children) online targeted at other online users, usually minors.

Online Safety: This term refers to web or online condition that guarantees a bullying-free, risk-free and threat-free surfing (use) of the Internet, especially by children.

Teenagers: This term refers to growing up children between the ages of 13 and 19 years old.

Youth: This term refers to certain age-brackets of young adults, usually between the ages of 17 and 30 years old.

The Nature, Extent, Causes, and Consequences of Cyberbullying

C

Michelle F. Wright

Masaryk University, Czech Republic

INTRODUCTION

Children and adolescents spend a great deal of time using and interacting through electronic technologies, including cell phones, gaming consoles, and the Internet. Some of their engagement with electronic technologies involves many benefits, such as the ability to engage in quick communication with just about anyone, including friends and family, and having access to a multitude of rich information. Despite the many opportunities afforded by electronic technologies, many children and adolescents are exposed to risks. One risk associated with electronic technology usage among adolescents and children is cyberbullying. Cyberbullying occurs through electronic technologies, including gaming consoles, email, instant messaging, chatrooms, social media, and text messages via mobile phones. The literature in this chapter draws on research from various disciplines, including communication, computer science, education, media studies, psychology, social work, and sociology. Furthermore, the literature involves a variety of different research designs, including cross-sectional and longitudinal methodologies as well as qualitative and quantitative designs. The chapter is organized into the following eight sections:

1. The first section provides a background of the nature of cyberbullying by focusing on defining it and describing the technologies used to target others and the features of anonymity as applied to cyberbullying.
2. The second section describes the extent of cyberbullying by focusing on the prevalence rates of children's and adolescents' involvement in cyberbullying.
3. The third section describes the individual characteristics and risks associated with children's and adolescents' involvement in cyberbullying.
4. The fourth section details the role of parents and families in children's and adolescents' cyberbullying perpetration and victimization.
5. Similar to the fourth section, the fifth section explains the role of peers and school in children's and adolescents' cyberbullying involvement.
6. The purpose of the sixth section is to review literature on the psychological, behavioral, and academic consequences associated with cyberbullying involvement among children and adolescents.
7. The seventh section discusses future research directions.
8. The final section provides concluding remarks on cyberbullying.

BACKGROUND

As deliberately embarrassing or intimidating, cyberbullying involves the usage of modern electronic technologies to harm others using hostile and repetitive behaviors (Wolak, Mitchell, & Finkelhor, 2007; Ybarra, West, & Leaf, 2007). Cyberbullying is described as an extension of traditional face-to-face bullying, and it also includes elements of an imbalance of power between the bully and the victim as well as the incorporation

DOI: 10.4018/978-1-5225-2255-3.ch150

of a technological component (Olweus, 1999). These behaviors are repetitive, deliberate, and intentionally carried out by bullies with malicious intent. Similar to traditional face-to-face bullying, cyberbullying can also include behaviors with a face-to-face equivalent, such as spreading a rumor about a victim, harassment, physical threats, social exclusion, humiliation, gossiping about a victim to get others not to like the victim, and/or verbal insults. There are also physical forms of cyberbullying, like in traditional face-to-face bullying, which can include hacking. It can include making anonymous phone calls, theft of identity information by pretending to be someone else, distributing explicit videos via various websites, and harassment using instant messenger, social networking websites, and text messages through mobile phones (Wolak et al., 2007; Ybarra & Mitchell, 2004). Other forms of cyberbullying involve happy slapping and flaming (Smith et al., 2008). Furthermore, cyberbullying can involve using various electronic technologies, instant messaging tools and social networking websites.

Researchers have attempted to understand why children and adolescents engage in cyberbullying. One proposal is that new electronic technologies allow cyberbullies to hide their identities, furthering the power differential between the cyberbully and the cybervictim (Wright, 2013; Ybarra et al., 2007). Many children and adolescents who engage in cyberbullying choose to remain anonymous while perpetrating cyberbullying (Dehue, Bolman, Vollink, & Pouwelse, 2012; Wright, 2014a; Ybarra & Mitchell, 2004). Another proposal relates to new electronic technologies' ability to allow the cyberbully to perpetrate frequent, repeated, and prolonged harassment (Wright, 2014a; Ybarra & Mitchell, 2004). Wright (2013; 2014a) found that when individuals felt more confidence in their ability to remain anonymous while using electronic technologies they engaged in more cyberbullying, especially when they could perpetrate cyberbullying anonymously.

THE EXTENT OF CYBERBULLYING

When an awareness of cyberbullying was gained by researchers, there were many studies conducted to understand how frequently children and adolescents were involved in these behaviors. In 2007, Wolak and colleagues (2007) conducted one of the earliest studies on cyberbullying in the United States. They found that 50% of children and adolescents in their sample were victimized by cyberbullying. Lower prevalence rates have been found in other studies conducted on cyberbullying involvement in the United States. For instance, Kowalski and Limber (2007) found that 11% of their 3,767 sample from middle school (aged 11-14) were victimized by cyberbullying, 4% had cyberbullied others, and 7% were classified as cyberbullies-cybervictims. Similar estimates were found in a study of cyberbullying by Patchin and Hinduja (2006). Among their sample, 29% of participants reported that they were cybervictims, while 47% reported to have witnessed cyberbullying at least once. More recent research revealed that 4.9% of children and adolescents in their sample ($N = 4,441$, 6-12th grade) were cybervictims within the past 30 days (Hinduja & Patchin, 2013).

Increasing evidence indicates that cyberbullying is not localized to one country. Instead, research has revealed that cyberbullying is a global concern. In one study, Cappadocia et al. (2013) found that out of their 1,972 sample of Canadian 10th graders, 2.1% perpetrated cyberbullying, 1.9% were cybervictims, and 0.6% were cyberbullies-cybervictims. Rates of cyberbullying involvement have also been examined in Australia as well. In this research, Campbell and colleagues (2012) found that 4.5% of their sample ($N = 3,112$; grades 6-12th) were victims of cyberbullying. Research has also documented cyberbullying involvement among European children and adolescents. Using a large sample of Swedish adolescents ($N = 22,544$; ages 15-18), Laftman et al. (2013)

found that 5% of their sample were classified as cybervictims, 4% as cyberbullies, and 2% as cyberbullies-cybervictims. Rates were similar for cyber victimization in Ireland and Belgium such that 6% of Irish adolescents ($N = 876$; ages 12–17; Corcoran, Connolly, & O'Moore, 2012) and 6.3% of Belgian adolescents ($N = 1,042$, M age = 15.47; Heirman & Walrave, 2012) were classified as cybervictims. Prevalence rates of cyber victimization were much higher among Italian adolescents. For instance, Brighi and colleagues (2012) found that 12.5% of the 2,326 Italian adolescents in their sample were cybervictims.

Although slower to develop, some research has focused on cyberbullying involvement rates among children and adolescents in Asia. In one study, Huang and Chou (2010) found that 63.4% of their sample ($N = 545$) witnessed cyberbullying, 34.9% were cybervictims, and 20.4% were cyberbullies. Jang and colleagues (2014) examined rates of cyberbullying involvement among Korean adolescents, with findings revealing that 43% of adolescents in their sample ($N = 3,238$) were cybervictims or perpetrators of cyberbullying. Among a sample of Chinese adolescents ($N = 1,438$), Zhou et al. (2013) found that 34.8% were cyberbullies and 56.9% were cybervictims. Rates were similar among a sample of 1,676 13 through 17 year olds in Singapore such that 59.4% were cybervictims through Facebook and 56.9% were cyberbullies through Facebook (Kwan & Skoric, 2013).

Comparisons of prevalence rates are difficult as the researchers relied on different samples and measurement of cyberbullying. Regardless of the shortcomings associated with studies on prevalence rates of cyberbullying involvement, it is clear that cyberbullying is a concern for children and adolescents around the world. Such a consideration highlights the importance of studying cyberbullying by attempting to understand the risk factors related to children's and adolescents' involvement in cyberbullying as victims, perpetrators, and bystanders.

CHARACTERISTICS AND RISK FACTORS ASSOCIATED WITH CYBERBULLYING INVOLVEMENT

C

After much of the research on the prevalence rates of cyberbullying involvement, many researchers directed their attention to understanding the characteristics and risk factors related to children's and adolescents' involvement in cyberbullying. Most of these earlier investigations focused on the role of demographic variables in cyberbullying perpetration and victimization. Age has been examined as a factor related to cyberbullying among children and adolescents. One study revealed that younger adolescents were at a greater risk of cyber victimization, while older adolescents were most frequently classified as cyberbullies (Ayas & Horzum, 2012). On the other hand, Wade and Beran (2011) found that 9th graders in their sample experienced the greatest risk of cyberbullying involvement when compared to adolescents in middle school. Such conflicting findings from studies focused on age indicated that this variable might be an inconsistent predictor of cyberbullying involvement. Gender is also another inconsistent predictor of cyberbullying involvement among children and adolescents. In particular, some researchers (Ybarra et al., 2007) have found that boys self-reported more cyberbullying perpetration when compared to girls, with some research revealing that girls experienced more cyber victimization in comparison to boys (Hinduja & Patchin, 2013; Kowalski & Limber, 2007). In contrast, some researchers (e.g., Dehue et al., 2012) have found that girls were more often the perpetrators of cyberbullying in comparison to boys, while boys were much more likely to be victims of cyberbullying (e.g., Huang & Chou, 2010). On the other hand, some researchers have found no gender differences in children's and adolescents' cyberbullying involvement (e.g., Wright & Li, 2013).

Some research has been conducted on other characteristics and risk factors associated with

cyberbullying involvement among children and adolescents. One risk factor for cyberbullying involvement is internet usage. In this research, cybervictims and cyberbullies typically report higher rates of chatting, emailing, blogging, gaming, and sending instant messages when compared to uninvolved children and adolescents (Smith et al., 2008; Ybarra & Mitchell, 2004). To explain the association between greater internet usage and cyberbullying involvement, Ybarra and colleagues (2007) proposed that cybervictims and cyberbullies are more likely to disclose personal information online, which worsens their exposure to online risks, such as cyberbullying. Thus, frequent internet usage increases children's and adolescents' willingness to disclose private information through electronic technologies. Higher normative beliefs concerning both traditional face-to-face bullying and cyberbullying were also related to cyberbullying perpetration among adolescents (Burton, Florell, & Wygant, 2013). Such findings indicate that cyberbullies view bullying behaviors as normal, which contributes to their perpetration of these behaviors. Defined as children's and adolescents' beliefs that bullying is unacceptable and that defending victims is valued, provictim attitudes are also related to cyberbullying perpetration. In particular, Elledge and colleagues (2013) found that holding lower levels of provictim attitudes were associated with greater cyberbullying perpetration. Other research has revealed that low self-control, less empathy, and moral disengagement are also contributors to cyberbullying perpetration (Jang et al., 2014; Robson & Witenberg, 2013).

Few studies have focused on the longitudinal risk factors related to cyberbullying involvement. Utilizing a longitudinal design, Fanti and colleagues' (2012) study revealed that media violence exposure, along with callous and unemotional traits, predicted cyberbullying perpetration one year later. Media violence exposure was also a risk factor associated with cyber victimization. Current research has indicated that perceived stress from parents, peers, and academics also increases

cyberbullying perpetration one year later among adolescents (Wright, in press). Considering each of the studies examined in this section, it is clear that there are a variety of individual characteristics and risk factors which make children and adolescents vulnerable to cyberbullying involvement. Other research has focused on the role of other individuals in children's and adolescents' involvement in cyberbullying. Parents and families have also been examined as having a role in children's and adolescents' cyberbullying perpetration and victimization.

THE ROLE OF PARENTS AND FAMILIES

Parental monitoring and parenting styles have been examined in relation to children's and adolescents' involvement in cyberbullying. Mason (2008) found that 30% of adolescents in his sample utilized the Internet for three hours or more daily, with 50% of these adolescents reporting that their parents monitored their activities. Even when parents do monitor their children's online activities, they are usually not effective because some parents lack technological skills and many do not follow-up on the strategies that they have implemented. In addition, many parents in one sample reported that they were not certain of what their children did online and they were less certain on how to discuss the topic of online activities with their children. Because parents are not able to engage in an active and ongoing dialogue with their children about online activities, and considering that experiencing online risks is almost inevitable for children, it is not likely that some children have the skills necessary to effectively deal with problematic situations that arise online.

Another line of research focuses on the associations between family characteristics and children's and adolescents' cyberbullying involvement. In this research, Ybarra and Mitchell (2004) revealed that lower caregiver monitoring and poor emotional bonds with caregivers were risk factors

associated with cyberbullying. They did not find evidence that family income, parental education, and caregiver status (single or married) were related to cyberbullying perpetration or cyber victimization. On the other hand, Aricak and colleagues' (2012) study revealed that parental unemployed increased children's and adolescents' risk of being involved in cyberbullying. Neglectful parenting is also a risk factor associated with cyberbullying perpetration and cyber victimization. In particular, Dehue and colleagues (2012) found that victims and perpetrators of cyberbullying were more likely to report that their parents engaged in neglectful parenting styles when compared to uninvolved children and adolescents. Similarly, their study also indicated that authoritarian parenting style increased children's and adolescents' risk of cyber victimization. More attention should be given to the role of parents and families in children's and adolescents' cyberbullying involvement.

THE ROLE OF SCHOOLS AND PEERS

Once children enter formal schooling, they spend most of their time in such settings until they graduate from high school or college. Consequently, some researchers have directed their attention to the linkages of peers and schools to children and adolescents' bullying involvement. Although schools' role in cyberbullying involvement is a bit complicated, some research has focused on how schools, particularly teachers and school climate, impact children's and adolescents' cyberbullying involvement. In one study, many teachers perceived the impact of overt forms of traditional face-to-face bullying as much worse than covert forms of bullying, like relational aggression and some forms of cyberbullying (Sahin, 2010). Cyberbullying and schools' involvement in these incidences is further complicated because many situations involving cyberbullying occur outside of school through electronic technologies. This makes it difficult for teachers to know about such

incidences and for them to intervene or provide support to the victim. Additionally, many teachers have not been properly trained on how to deal with and recognize cyberbully behaviors as well as the risk factors associated with these behaviors, furthering hindering schools' ability to deal with these behaviors. Cassidy and colleagues (2012a) found that some of the Canadian teachers in their sample were unfamiliar with some of the newer electronic technologies. Their lack of knowledge made it difficult for them to deal with cyberbullying, even if a victim came to them for help.

A negative school climate and lower school commitment increase cyberbullying perpetration at schools (Ybarra & Mitchell, 2004). Another problem inhibiting schools' ability to deal with cyberbullying is that there are few implemented policies and programs, even when teachers were concerned with these behaviors. It is important that teachers are concerned about cyberbullying and understand how to prevent it. Teachers' motivations for learning about cyberbullying and their self-efficacy for believing in their ability to deal with these behaviors decreased from elementary school to middle school.

Another feature of the school environment are children's and adolescents' peers. Festl and colleagues (2013) examined the role of peers in adolescents' cyberbullying involvement. Their findings revealed that one of the best predictors of cyberbullying involvement were classrooms in which the highest incidences of cyberbullying occurred. In addition, adolescents who believed that their friends perpetrated cyberbullying were more likely to perpetrate these behaviors as well (Hinduja & Patchin, 2013). Some research has focused on the quality of peer relationships to understand children's and adolescents' involvement in cyberbullying. In particular, Burton and colleagues (2013) found that higher levels of peer attachment were related negatively to cyberbullying perpetration and cyber victimization. In addition, being rejected by one's peers was also related to cyberbullying, even after controlling for face-to-face victimization (Wright & Li, 2013).

Research has also revealed that cyberbullying perpetration might be used to boost adolescents' social status among their peer group. For example, Wright's (2014b) study suggested that higher levels of perceived popularity, a reputational type of popularity usually linked to traditional face-to-face bullying perpetration, increased adolescents' cyberbullying perpetration six months later.

PSYCHOLOGICAL, BEHAVIORAL, AND ACADEMIC DIFFICULTIES

Researchers, educators, and parents are particularly concerned about the psychological, behavioral, and academic difficulties associated with adolescents experiencing and/or perpetrating cyberbullying. Perpetrators and victims of cyberbullying reported internalizing difficulties, such as depression and anxiety, and externalizing difficulties, including drug and alcohol use as well as violence (Patchin & Hinduja, 2006; Ybarra et al., 2007). Cyberbullying involvement is also linked to problems in school. In one study, Wright (2015) examined the longitudinal associations between school functioning and cyberbullying involvement. She found that cyberbullying perpetration and cyber victimization were each associated with poor academic performance, absenteeism, and school behavioral problems (e.g., classroom disruptions) one year later.

The bulk of the research on the psychological, academic, and behavioral difficulties associated with children's and adolescents' cyberbullying involvement do not control for traditional face-to-face bullying involvement. Controlling for these variables is important as there are strong correlations between cyberbullying involvement and traditional face-to-face bullying involvement. To this end, Bonanno and colleagues (2013) examined cyberbullying perpetration and cyber victimization in relation to depressive symptoms and suicidal ideation. After including face-to-face bullying and victimization in the same model, they

still found associations between these variables. However, Brighi and colleagues (2012) did not find a relationship between cyber victimization and loneliness or self-esteem, after accounting for traditional face-to-face bullying victimization.

FURTHER RESEARCH DIRECTIONS

There are a variety of gaps in the cyberbullying literature, which need to be investigated through future research. One recommendation is that follow-up research needs to focus on understanding more about the concept of anonymity as applied to cyberbullying. Anonymity is not only a component of cyberbullying, but anonymous forms of traditional face-to-face bullying can occur as well. For example, a nasty note can be slipped into a peer's locker anonymously. Thus, research should be conducted to understand differences in children's and adolescents' conceptualizations of anonymous acts in the cyber context and the offline world. There are few longitudinal studies conducted on cyberbullying involvement. In future research, longitudinal designs should be utilized to examine both traditional face-to-face bullying and cyberbullying involvement from childhood into late adolescence or even emerging adulthood. Investigations focused on the developmental trajectory of bullying involvement in both social contexts are important as much of the research on cyberbullying does not take into account previous levels of traditional face-to-face bullying, although these variables are strongly correlated (Wright & Li, 2013; Ybarra et al., 2007).

CONCLUSION

This chapter reviewed the nature, extent, causes, and consequences associated with cyberbullying. Researchers are beginning to understand that attacks which occur in cyberspace might be just as powerful as face-to-face attacks. Our communities

need to recognize this threat and devote time to dealing with it, as it affects everyone. Cyberbullying will probably not disappear anytime soon, due to our increasing reliance of electronic technologies. Therefore, we all must stand united in our efforts to reduce or prevent cyberbullying.

KEY TERMS AND DEFINITIONS

Cyberbullying: When young people harass, humiliate, embarrass, intimidate, and/or threaten another young person via information and communication technologies.

Cyber Victimization: When young people experience harassment, humiliation, embar-

rassment, intimidation, and/or are threaten via information and communication technologies by another young person.

Face-to-Face Bullying: When young people harass, humiliate, embarrass, intimidate, and/or threaten another young person offline.

Face-to-Face Victimization: When young people experience harassment, humiliation, embarrassment, intimidation, and/or are threaten offline by another young person.

Information and Communication Technologies: This board term encompasses communication device or applications, such as computers and cellular phones.

Parental Involvement: Involves the participation of parents in their children's activities.

Parental Mediation of Technology Use: The strategies parents use to control, supervise, or interpret information and communication technology content for their children.

Peer Attachment: The feelings and beliefs that one's peers will be there when needed.

School Climate: The quality and character of school life, which includes norms, values, interpersonal relationships, social interactions, and organizational processes and structures.

Data Analysis and Statistics

Advanced Recommender Systems

D**Young Park**

Bradley University, USA

INTRODUCTION

It is increasingly difficult to find the right information on the Web in the age of explosive information overload. Recommender systems provide users with personalized suggestions of goods, services, or information and thus help them find the most relevant and interesting goods, services, or information for them. Over the last two decades since the first major recommender systems emerged in the mid-1990s (Konstan et al., 1997; Resnick & Varian, 1997), numerous recommender systems have been developed and used in various application domains including e-commerce, education, and engineering (Aggarwal, 2016; Jannach, Zanker, Felfernig, & Friedrich, 2011; Manouselis, Drachsler, Verbert, & Santos, 2014; Ricci, Rokach, & Shapira, 2015; Robillard, Maalej, Walker, & Zimmermann, 2014). Recommender systems have also proven very useful in various application domains.

A basic personalized recommender system suggests a list of items that seem to be most relevant for a given single target user without considering the context that the user is in by using users' ratings of items on a single overall criterion where both users and items are in a single domain (Jannach et al., 2011). The basic recommender system can be extended in several ways. There are four major extensions, i.e., suggesting items for a group of target users rather than a single user (group recommendations), suggesting items by considering a specific context of the target user (context-aware recommendations), suggesting items using ratings on multiple criteria rather than a single overall criterion (multi-criteria recommendations), and suggesting items by using users and items in

multiple domains rather than a single domain (multiple-domain recommendations).

In this chapter, we present a brief and systematic overview of four major advanced recommender systems — *group* recommender systems, *context-aware* recommender systems, *multi-criteria* recommender systems, and *cross-domain* recommender systems. We characterize and compare them within a unifying model as extensions of the basic recommender systems. Future research topics and directions in the area of advanced personalized recommendations are discussed.

BACKGROUND

Recommender Systems (RS)

A *recommender system (RS)* is a software-intensive system that provides a given target users with personalized recommendations of items such as goods, services, or information to guide the user to find the most relevant items (Aggarwal, 2016; Jannach et al., 2011; Ricci et al., 2015). The personalized recommendations are made by using profiles of the target user and other users with respect to items.

A typical recommender system generally uses the following three types of data — data about the users (U), data about the items such as goods, services, or information (I), and data about the relevance (such as rating, evaluation, purchase, or interest) information between the users and the items (R) where

- U contains a set of all existing users.
- I contains a set of all existing items.

- R contains relevance ratings of items to users that are represented as a matrix that maps a user-item pair into a relevance value and are constructed over time either explicitly, inferred implicitly, or both.

Given a target user T , a recommender system recommends a list of new items that are likely to be most relevant to the target user by using U , I , and R . The personalized recommendation process generally uses two phases: the prediction phase and the suggestion phase. The prediction phase predicts the unknown relevance values of new items by the target user based on the *similarity* between users or between items. There are a number of similarity metrics including *Pearson correlation* and *Cosine similarity* to represent the degree of similarity between users or items (Jannach et al., 2011). The suggestion phase generates a list of top n items with the highest predicted relevance values. Various metrics such as *mean absolute error* (MAE), *mean square error* (MSE), *root mean squared error* (RMSE), *precision* and *recall* are used for evaluating the accuracy of the recommended items (Herlocker, Konstan, Terveen, & Riedl, 2004; Jannach et al., 2011).

There are a number of different approaches for generating personalized recommendations. Three major approaches for personalized recommendations are *collaborative recommender*, *content-based recommender* and *hybrid recommender*. For recommending relatively complex items there is an approach called *knowledge-based recommender* that is based on deep domain *knowledge* about users and items.

Collaborative filtering-based recommendation is based on *user collaborations* and is the most widely used and proven method of providing recommendations (Ekstrand, Riedl, & Konstan, 2011; Schafer, Frankowski, Herlocker, & Sen, 2007). There are two types of collaborative filtering: *neighborhood-based collaborative filtering* such as user-based collaborative recommender and item-based collaborative recommender (Linden, Smith, & York, 2003) and *model-based collab-*

orative filtering (Koren, Bell, & Volinsky, 2009). The collaborative filtering-based recommenders, however, have the relevance feedback sparsity problem and the new item problem. Content-based recommendation is based on the *content* of items (Lops, Gemmis, & Semeraro, 2011; Pazzani & Billsus, 2007). The content-based recommender recommends a list of items with similar content to the items that the target user gave good ratings. But, content-based recommendation has limitations such as the item overspecialization problem and the new user problem. Hybrid recommendation recommends items via *hybridization*, i.e., by combining the content-based recommendation and the collaborative filtering-based recommendation together (Burke, 2007).

Basic Recommendation

We will use a model of basic personalized recommendation to characterize advanced recommendations as extensions of the basic model. We define the *basic recommender system* (BRS) as a collaborative recommender system that recommends a list of items:

- For a single target user,
- In a single context,
- By using users' ratings of items on a single overall relevance criterion,
- where both users and items are in a single domain.

Figure 1 depicts the overall architecture of our basic personalized recommender system that is represented as *single target user*, *single context*, *single relevance criterion* & *single domain*.

ADVANCED RECOMMENDATIONS

There are four major advanced recommendations, i.e., group recommendation, context-aware recommendation, multi-criteria recommendation, and cross-domain recommendation. We comparatively

Figure 1. Basic personalized recommendation – Single target user, single context, single relevance criterion & single domain

characterize these major advanced recommendations as extensions of the basic personalized recommendation model shown in Figure 1 in a unifying framework.

Group Recommender Systems (GRS)

Basic recommender systems recommend a list of items most relevant to a single individual user. However, there are many situations that call for recommendations of relevant items for a group of users instead of a single user, for example, restaurant recommendation for a user and the user's friends (Berkovsky & Freyne, 2010; Jameson & Smyth, 2007; Kompan & Bielikova, 2014;

Masthoff, 2011). The recommendations are shared by the group of users.

A *group recommender system* (GRS) is a recommender system that provides a group of users with a shared list of items that are most relevant to the users in the group.

Group recommendation as an extension of the basic single-user recommendation is illustrated in Figure 2. Groups can be real or virtual. There can be different types of groups, such as established groups, occasional groups, random groups, and automatically identified groups.

We generate group recommendations using the basic single-user recommender system. There are three general approaches for the group recom-

Figure 2. Group recommendation – Group of target users

Figure 3. Context-aware recommendation – Multiple contexts

mendation process (Berkovsky & Freyne, 2010; Jameson & Smyth, 2007; Kompan & Bielikova, 2014; Masthoff, 2011):

Approach 1: Aggregate the users $u_1, u_2, \dots, u_k$ in the group into a single aggregated group user $u_{\text{aggregated}}$ and apply the single-user recommender system to the aggregated group user $u_{\text{aggregated}}$ to produce the group recommendation of items.

Approach 2: Apply the single-user recommender system to each user u_i for $i = 1, 2, \dots, k$ in the group and aggregate k single-user recommendations of items into the group recommendation of items.

Approach 3: Represent the whole group of target users as a single user u_{group} and apply the single-user recommendation to the user u_{group} to produce the group recommendation of items.

Various aggregation strategies can be used for user and recommendation aggregation, including additive strategy, multiplicative strategy, plurality strategy, fairness strategy, average strategy, least misery strategy, and most pleasure strategy. Most aggregation strategies seem to show similar results.

Group recommendation can be used for the cold start problem with new users. Many group recommenders have been proposed in various

application domains, including movies, songs, books, television programs, news, restaurants, recipes, tours, and learning.

Context-Aware Recommender Systems (CARS)

A basic recommender system recommends a list of items most relevant to a target user without considering any additional specific contextual information about the user. However, in many situations, recommendations of more relevant items need additional contextual information about the target user (Adomavicius, Mobasher, Ricci & Tuzhilin, 2011; Adomavicius & Tuzhilin, 2011; Liu, Ma, Chen, & Xiong, 2013; Panniello & Gorgoglione, 2011; Symeonidis, Ntempos, & Manolopoulos, 2014). For example, more enhanced recommendation of music can be possible by considering contexts like the location, time, and mood of a user. This additional contextual information can provide better recommendations.

A *context-aware recommender system* (CARS) is a recommender system that provides a target user within a specific context with a list of items that are most relevant to that user in that context.

Figure 3 shows context-aware rating recommendation as an extension of the basic single-context rating recommendation.

Contextual information in recommender systems is the context in which recommendations are provided to a target user, such as time, location, surroundings, companions, occasions, and so on. Time is a useful context and used in time-aware recommendations (Campos, Díez, & Cantador, 2014). Location is an important contextual information in mobile environments for location-aware recommendations (del Carmen, Ilarri, Trillo-Lado, & Hermoso, 2015; Levandoski, Sarwat, Eldawy, & Mokbel, 2012).

We can incorporate contextual information in the basic single-context recommender system in order to generate context-aware recommendations in the following three ways (Adomavicius et al., 2011; Adomavicius & Tuzhilin, 2011; Panniello & Gorgoglione, 2011):

Approach 1: Select the user-item ratings R_c for a given specific context c from the all-context user-item ratings R_1 to R_k (called *contextual pre-processing*), and then apply basic single-context rating recommendation using the user-item ratings R_c in the context c for a given target user u to produce the contextual recommendation of items.

Approach 2: Apply basic single-context rating recommendation using the all-context user-item ratings R_1 to R_k to produce the recommendation of items for all contexts for a given target user u , and then select the contextual recommendation of items for a given context c from the recommendation of items for all contexts (called *contextual post-processing*).

Approach 3: Apply either a similarity-based or a model-based multidimensional rating recommendation for a given target user u and a given context c to produce the contextual recommendation of items (called *contextual modeling*).

These three approaches can be combined to improve recommendation accuracy. Various context-aware recommenders have been proposed

in several mobile application domains, such as restaurant, travel, tour, learning, and shared economy.

Multi-Criteria Recommender Systems (MCRS)

Basic recommender systems recommend a list of most relevant items by using the relevance ratings of items provided by users in a single criterion of overall relevance. However, there are many situations in which the recommendation process requires more information than just single overall relevance ratings, i.e., relevance ratings of items in many aspects (Adomavicius & Kwon, 2007; Adomavicius, Manouselis, & Kwon, 2011; Lakiotaki, Matsatsinis, & Tsoukias, 2011; Manouselis & Costopoulou, 2007). For example, hotels can be rated on many dimensions such as the room, the service, and the neighborhood, as well as overall satisfaction. This additional information can enhance recommendation quality.

A *multi-criteria recommender system* (MCRS) is a recommender system that provides a target user with a list of items that are most relevant to that user by using the relevance ratings of items in multiple criteria that are provided by the users.

Multi-criteria rating recommendation as an extension of the basic single-criterion rating recommendation is shown in Figure 4. Here, r_i is the rating in overall criterion c_i and r_i for $i = 2, 3, \dots$, k is the rating in each criterion c_i for $i = 2, 3, \dots$, k .

Figure 4. Multi-criteria recommendation – Multiple relevance criteria

Figure 5. Cross-domain recommendation – Multiple domains

To generate multi-criteria recommendations, we incorporate multi-criteria rating information during the rating prediction phase and the item suggestion phase of the basic single-criterion recommender system (Adomavicius & Kwon, 2007; Adomavicius et al., 2011; Lakiotaki et al., 2011).

In the neighborhood-based rating prediction phase, we use the following two approaches to incorporate the multi-criteria ratings:

Approach 1: Compute for each criterion c_i for $i = 1, 2, 3, \dots, k$ the similarity between two users using some similarity measure in the single-criterion rating recommender system. Then, compute the overall similarity between two users by aggregating these k similarities in individual criteria using some aggregation strategy such as average similarity, worst-case similarity, or aggregated (weighted sum of individual similarities) similarity.

Approach 2: Compute the overall similarity between two users using some multidimensional distance similarity measure such as Manhattan distance, Euclidean distance, or maximal value distance.

In the model-based rating prediction phase, approaches for incorporating the multi-criteria ratings include the aggregation function approach, the probabilistic modeling approach, and the multilinear singular value decomposition approach.

In the aggregation function approach, the overall rating is viewed as an aggregate of other criteria ratings and the relationship is modeled as an aggregate function of other criteria ratings.

The multi-criteria ratings can also be used in the item suggestion phase if the overall rating criterion is not available. A number of multi-criteria recommenders have been proposed in various application domains including movies, music, books, restaurants, hotels, tours, and learning.

Cross-Domain Recommender Systems (CDRS)

A basic recommender system suggests a list of most relevant items in a single domain (such as movies or books) and is thus a domain-specific recommender system. In many cases, the same users provide relevant ratings of different types of items, like movies and books, in different domains (Cantador, Fernández Tobías, Berkovsky, & Cremonesi, 2015; Dong, 2012; Fernández-Tobías, Cantador, Kaminskas, & Ricci, 2012; Li, 2011). For domains that share some resources like users, items and ratings, knowledge from one domain (the source domain) can be exploited in and transferred to better recommendations in another domain (the target domain).

A *cross-domain recommender system* (CDRS) is a recommender system that provides a target user with a list of items in the target domain that

are most relevant to the target user by exploiting knowledge from the source domain that shares resources with the target domain.

Figure 5. illustrates cross-domain rating recommendation as an extension of the basic single-domain rating recommendation. Domains can be defined at different levels, such as item attribute level, item type level, item level, and system level. Resource sharing between the source and target domains can be both user and item overlap, user overlap only, item overlap only, and no overlap.

In general, there are two approaches to incorporating knowledge from the source domain to the target domain for cross-domain recommendations (Cantador et al., 2015; Fernández-Tobías et al.2012):

Approach 1: Aggregate knowledge from the source domain(s) to produce recommendations of items in the target domain (called *knowledge aggregation*).

Approach 2: Link and transfer knowledge from the source domain(s) to produce recommendations of items in the target domain (called *knowledge linkage and transfer*).

There are various techniques for knowledge aggregation across domains:

- Merge user ratings and apply the single-domain recommender system to the merged ratings to produce the target domain recommendation.
- Build user modeling from the source domain for use in applying the single-domain recommender system to the target domain to produce the target domain recommendation.
- Apply the single-domain recommender system to the source domain and the target domain and combine the two resulting recommendations to produce the target domain recommendation.

There are several techniques for knowledge linkage and knowledge transfer across domains:

- Link items in the source and target domains using some common knowledge.
- Share common latent features between the source and target domains.
- Transfer rating patterns between the source and target domains.

Cross-domain rating recommendation can address the cold start problem and the sparsity problem, and thus enhance recommendation accuracy. Various cross-domain recommenders have been proposed in several application domains including movies, television shows, music, books, and restaurants.

FUTURE RESEARCH DIRECTIONS

Advanced recommender systems such as group recommendation, context-aware recommendation, multi-criteria recommendation, and cross-domain recommendation are all relatively new research areas presenting many underexplored and open research topics.

Possible future research topics in the area of group recommender systems may include subareas such as modeling users and groups, aggregation strategies, incorporating personality and social aspects, explaining group recommendations, privacy and security issues in group recommendations, experimental evaluation, new application domains, and the connection with multi-criteria recommendations.

In the area of context-aware recommendation, interesting future topics may include modeling contexts, strategies for context incorporation, explaining context-aware recommendations, context suggestions, evaluation on practical applications, new application domains, and the connection with mobile recommendations.

Topics like building criteria for items, selecting the best set of criteria, collecting real-world datasets for experimental evaluation, new application domains, and the connection with group recommendations are possible research subareas in the area of multi-criteria recommender systems.

Incorporating knowledge from the source domain, real-world cross-domain datasets for experimental evaluation, new application domains, and the connection with context-aware recommendations are interesting future research topics in the area of cross-domain recommender systems.

Most current research has focused on each advanced recommendation separately, but combining different advanced recommendations opens new and exciting possibilities for the future.

CONCLUSION

We have presented a systematic overview of four major advanced recommender systems. We have comparatively characterized group recommender systems, context-aware recommender systems, multi-criteria recommender systems, and cross-domain recommender systems within a unifying model as extensions of basic recommender systems. Future research directions in the area of advanced personalized recommendation have been discussed. We believe that advanced recommender technologies will continue to advance.

KEY TERMS AND DEFINITIONS

Advanced Recommendation: Personalized recommendation as an extension of basic recommendation such as group recommender systems, context-aware recommender systems, multi-criteria recommender systems, and cross-domain recommender systems.

Basic Personalized Recommendation: Personalized recommendation of items for a single target user in a single context by using users' ratings of items on a single overall relevance criterion where both users and items are in a single domain.

Collaborative Recommender System: A recommender system that recommends items through user collaborations and are the most widely used and proven method of providing personalized recommendations. There are three major types: user-to-user collaborative filtering based on user-to-user similarity, item-to-item collaborative filtering based on item-to-item similarity, and latent factor model-based collaborative filtering based on user-item matrix factorization.

Context-Aware Recommender System: A recommender system that provides a target user within a specific context with a list of items that are most relevant to the target user in the specific context.

Cross-Domain Recommender System: A recommender system that provides a target user

with a list of items in the target domain that are most relevant to the target user by exploiting knowledge from the source domain that shares resources with the target domain.

Group Recommender System: A recommender system that provides a group of users as a whole with a shared list of items that are most relevant to the users in the group.

Multi-Criteria Recommender System: A recommender system that provides a target user with a list of items that are most relevant to the target user by using the relevance ratings of items in multiple criteria that are provided by the users.

Recommender System: A software system that provides a single target user within a single context with personalized recommendations of items such as goods, services or information to guide the target user to find most relevant items using ratings on a single relevance criterion (i.e., overall) and where both users and items are in a single domain.

Centrality Analysis of the United States Network Graph

Natarajan Meghanathan
Jackson State University, USA

INTRODUCTION

Network Science is one of the emerging fields of Data Science to analyze real-world networks from a graph theory point of view. Several real-world networks have been successfully modeled as undirected and directed graphs to study the intrinsic structural properties of the networks as well as the topological importance of nodes in these networks. The real-world networks that have been subjected to complex network analysis typically fall under one of these categories: social networks (Ghali et. al., 2012), transportation networks (Cheung & Gunes, 2012), biological networks (Ma & Gao, 2012), citation networks (Zhao & Strotmann, 2015), co-authorship networks (Ding, 2011) and etc. One category of real-world networks for which sufficient attention has not yet been given are the regional networks featuring the states within a country. In this chapter, we present a comprehensive analysis of a network graph of the states within a country with respect to the four commonly used centrality metrics in complex network analysis (Newman, 2010): degree, eigenvector, betweenness and closeness centralities.

We opine the chapter to serve as a model for anyone interested in analyzing a connected graph of the states within a country from a Network Science perspective. The approaches presented in this chapter could be useful to determine the states (and their cities) that are the most central and/or influential within a country. For example, the ranking of the vertices based on the shortest path centrality metrics (closeness and betweenness) could be useful to choose the states (and their cities) that could serve as hubs for transportation

networks (like road and airline networks). We could identify the states that are most the central states as well as identify the states that could form a connected backbone and geographically well-connected to the rest of the states within a country and use this information to design the road/rail transportation networks. The degree centrality and eigenvector centrality metrics as well as the network-level metrics like minimum connected dominating set and maximal clique size could be useful to identify fewer number of venues (with several adjacent states to draw people) for political campaigns/meetings that would cover the entire country.

We choose the United States (US) as the country for analysis and build a connected network graph of the contiguous states (48 states and the District of Columbia, DC) of the US: each state and DC is a node (vertex) and there exists a link (edge) between two vertices if the two corresponding states/DC share a common border. Though some prior studies have been conducted on transportation networks (Cheung & Gunes, 2012) and food flow networks (Lin et. al., 2014) in the United States, to the best of our knowledge, there has been no prior study of centrality analysis on the graph of the contiguous US states solely based on their geographical locations. Table 1 lists the contiguous states and DC in alphabetical order, their two character codes and the IDs used to refer to them in the chapter. The rest of the chapter is organized as follows: Section 2 introduces the centrality metrics and presents the results of the analysis on the states graph for each of them. Section 3 discusses related work. Section 4 concludes the chapter by summarizing the results

Table 1. List of contiguous states (including DC) of the US in alphabetical order

ID	State/District Name	Code	ID	State Name	Code	ID	State Name	Code

16	Kentucky	KY	33	North Dakota	ND	49	Wyoming	WY
17	Louisiana	LA						

of Section 2. For the rest of the chapter, the terms ‘network’ and ‘graph’, ‘node’ and ‘vertex’, ‘link’ and ‘edge’ are used interchangeably. They mean the same. The layout for the US States Network graph presented in Figure 1 is drawn using the Fruchterman Reingold layout algorithm (Fruchterman and Reingold, 1991), available in Gephi (Cherven, 2013).

BACKGROUND

Centrality Metrics

In this section, we introduce the centrality metrics for which we will run their respective algorithms on the US States Network graph and present the results (including their distribution and ranking of the vertices). The four centrality metrics analyzed are: degree centrality, eigenvector centrality, closeness centrality and betweenness centrality.

Since the US States graph is an undirected graph, the adjacency matrix of the graph is symmetric and there is only one value per vertex for each centrality metric.

Degree Centrality

The degree centrality (DegC) of a vertex is the number of edges incident on it. Table 2 presents the degree centrality of the vertices and the corresponding rank (in the decreasing order of their values) in the US States network graph; vertices with identical values for DegC have the same rank. The state of Missouri has the largest degree centrality value of 9, followed by the state of Tennessee with the second largest degree centrality value of 8. The state of Maine has the smallest degree centrality value of 1 (as New Hampshire is its only adjacent state). There are no ties among vertices for the largest and second largest values of degree centrality as well as for the vertex with

Figure 1. Fruchterman Reingold layout of the US network states graph

the smallest degree centrality. However, as we can notice (from Table 2): for other values of degree centrality, there are several instances of ties among vertices (we assign the same rank for all such vertices with identical values for degree centrality).

Figure 2 illustrates the cumulative and non-cumulative degree distributions of the vertices in the states graph. The cumulative distribution curve indicates that more than 85% of the vertices have degree of 6 or lower (the degree values are mostly ± 1 away from either of the two peaks), even though the largest degree observed is 9. The non-cumulative distribution curve illustrates that the degree distribution is bi-modal with a Poisson pattern (Balakrishnan & Nevzorov, 2003) with the peaks observed at degree values of 3 and 5. To corroborate this assertion, we observe the average degree of the vertices to be 4.37 (roughly close to the average of the two peak degree values of 3 and 5), with a standard deviation and Kurtosis

of 1.72 and 2.75 respectively (all indicating that the degree distribution is close to being a normal/Poisson distribution; Balakrishnan & Nevzorov, 2003). Kurtosis is a measure of the “tailedness” of a probability distribution (Balanda & MacGillivray, 1988). For normal distribution, the expected value for the Kurtosis is 3; distributions with Kurtosis values above or below 3 are said to be fat-tailed and thin-tailed respectively (Balanda & MacGillivray, 1988). Further, the spectral radius ratio for node degree (defined as the ratio of the principal eigenvalue of the adjacency matrix of the graph and the average node degree; Meghanathan, 2014) is observed to be 1.24. The spectral radius ratio for node degree is a measure of the variation in node degree of the vertices; the minimum possible value for this metric is 1.0 and farther the value of the spectral radius ratio for node degree from 1, the larger is the variation in node degree. Though the spectral radius ratio for node degree value of 1.24 is not much farther from 1, the value is not

Table 2. Ranking of the vertices in the US states network graph based on degree centrality

Rank	ID	DegC	Rank	ID	DegC	Rank	ID	DegC	Rank	ID	DegC
1	24	9	5	2	5	6	23	4	7	48	3

Figure 2. Bi-modal poisson distribution (non-cumulative and cumulative) for the degree centrality metric of the US states graph

as close to 1 (Meghanathan, 2014) as observed for the US Football network (Girvan & Newman, 2002): a network with a unimodal Poisson degree distribution of the vertices; the value of 1.24 could be attributed to the variation due to the bi-modal degree distribution of the vertices.

Eigenvector Centrality

The eigenvector centrality (EVC) of a vertex is a measure of the degree of the vertex as well as the degree of its neighbors. A vertex is likely to have a higher EVC if it has a larger degree and its neighbor(s) also have a larger degree. The

EVC for a vertex corresponds to the entry for the vertex in the principal eigenvector of the adjacency matrix of the graph (Chung, 2006). The EVC of the vertices is computed by implementing the power-iteration algorithm [(Lay et al., 2015). Table 3 lists the EVC values (rounded to four decimal places) of the vertices in the US States graph. We observe a tie between the states of Vermont and Connecticut (values of 0.0050 each). The rest of the 47 vertices have a unique ranking. The US States graph is another example to illustrate that (unlike the degree centrality metric) the eigenvector centrality metric is more likely to return unique values for the vertices in

Table 3. Ranking of the vertices in the US states network graph based on Eigenvector Centrality

Rank	ID	EVC	Rank	ID	EVC	Rank	ID	EVC	Rank	ID	EVC
1	24	0.3697	14	11	0.1703	26	48	0.0951	38	21	0.0380

13	30	0.1720									

real-world network graphs (Meghanathan, 2015). The state of Missouri has the largest EVC value (0.3697), distantly followed by the states of Nebraska (0.2605) and Tennessee (0.2546); the state of Maine has the lowest EVC value (0.0004), far away from the immediately larger value of 0.0020 for the state of Rhode Island. The largest values for the state of Missouri with respect to both the degree centrality and eigenvector centrality metrics indicate that the state of Missouri not only has the largest degree, its neighboring states also have a relatively larger degree.

Figure 3 illustrates the cumulative probability distribution of the EVC values of the vertices in the US States graph. Except the state of Missouri

(that has an EVC value much larger than the rest of the vertices), each of the other states have an EVC value that is closer to one or two other states. Thus, the distribution of the EVC values of the vertices follows a Poisson distribution. Figure 3b presents a comparison of the degree centrality and eigenvector centrality values of the vertices and the Spearman's rank-based correlation coefficient (Daniel, 2000) between the two degree-based centrality metrics is 0.80. We observe that vertices with the same degree centrality have a wide range of values for the eigenvector centrality. Though vertices with larger degree centrality appear to be more likely to have a larger eigenvector centrality, there are several vertices

Figure 3. Eigenvector Centrality of the vertices in the us states graph

for which the eigenvector centrality is relatively lower (compared to the EVC of vertices that have a relatively lower degree centrality) even if they have a higher degree centrality. For example, the state of Massachusetts (degree centrality - 5) has a much lower EVC (0.0061) than the state of Georgia (degree centrality - 3; EVC - 0.0946): primarily, attributed to the relatively higher degree of the neighbors for the state of Georgia.

Betweenness Centrality

The Betweenness Centrality (BWC) of a vertex is a measure of its presence among the shortest paths between any two vertices in the graph (Newman, 2010). The BWC of a vertex v_i is the sum of the fractions of the shortest paths between any two vertices (v_j and v_k ; $i \neq j \neq k$) that go through v_i . Quantitatively (Newman, 2010),

$$BWC(i) = \sum_{j \neq k \neq i} \frac{sp_{jk}(i)}{sp_{jk}}, \text{ where } sp_{jk} \text{ is the total}$$

number of shortest paths between vertices v_j and v_k ; $sp_{jk}(i)$ is the number of such shortest paths between v_j and v_k that go through vertex v_i . We determine the BWC of the vertices in the US States graph by implementing the Brandes' algorithm

(Brandes, 2001). Table 4 ranks the vertices in the US States graph based on BWC; the state of Missouri has the largest BWC value (821.4), followed by the states of Kentucky (602.4) and Pennsylvania (554.4). Seven vertices (DC, Florida, Maine, Michigan, Rhode Island, South Carolina and Washington) have a BWC value of 0.0 - indicating that these vertices do not lie on the shortest path between any two vertices in the graph. In addition to the above tie, when rounded to the first decimal value for the non-zero values of BWC, we notice that there are ties between Delaware and New Jersey (with a lower BWC of 7.0 each). A total of 42 distinct rank values could be assigned for the vertices.

Figure 4 illustrates the cumulative probability distribution of the BWC of the vertices. We notice that about 81% of the vertices have BWC values less than 180; while the largest BWC value observed is 821.4. Thus, the BWC metric exhibits a Power-law style distribution (Balakrishnan & Nevzorov, 2003) for the vertices in the US States graph. From Figure 4b, we also notice that though vertices with a higher degree are more likely to have a higher BWC and the Spearman's rank-based correlation coefficient is 0.87; we do observe instances wherein the BWC values could vary

Table 4. Ranking of the vertices in the US states network graph based on Betweenness Centrality

Figure 4. Betweenness Centrality of the vertices in the US states graph

appreciably even among vertices with the same degree centrality.

Closeness Centrality

The Closeness Centrality (CIC) of a vertex is a measure of the number of hops on the shortest paths from the vertex to every other vertex in the graph (Newman, 2010). The CIC of a vertex is the inverse of the sum of the lengths (hops) of the shortest paths from the vertex to the rest of the vertices in the graph (determined using the Breadth First Search algorithm; Cormen et. al., 2009). We observe the state of Missouri to have the largest CIC, followed by the states of Kentucky and Tennessee. The state of Maine has the lowest

CIC indicating that the sum of the length of the shortest paths from this state to the rest of the states is the largest. From Table 5, a total of 40 unique values could be observed for the CIC of the vertices (there are several instances where two or three states have the same values for the CIC). Figure 5a captures the cumulative distribution of the CIC; we observe the values to be uniformly distributed albeit within a smaller range (unlike the EVC and BWC) resulting in a relatively steep curve. Figure 5b captures the relationship between degree centrality and closeness centrality; vertices with a larger degree are likely to have a larger closeness centrality and the Spearman's rank-based correlation coefficient value is 0.75.

Table 5. Ranking of the vertices in the US states network graph based on Closeness Centrality

Figure 5. Closeness Centrality of the vertices in the US states graph

Figure 6. Relationship between Eigenvector, Closeness and Betweenness Centrality metrics for the US states graph

Ranking of Vertices based on the Centrality Metrics

Figures 3, 4 and 5 respectively capture the relationship between degree centrality and each of the other three centrality metrics (EVC, BWC and CIC). Figures 6a, 6b and 6c capture the relationship between EVC, BWC and CIC. We present the values for the Spearman's rank-based correlation coefficient between any two centrality metrics in Table 6. The larger the value of the correlation coefficient for any two metrics, the more the similarity in the ranking of the vertices with respect to the two metrics in consideration. We observe the ranking between DegC and BWC to have the highest correlation coefficient (0.87), whereas the ranking between EVC and BWC has the lowest cor-

relation coefficient (0.52). The lower correlation coefficient values for EVC-BWC and BWC-CIC metrics indicate the rankings of the vertices with respect to each of the two combinations are quite different from each other. Nevertheless, the state of Missouri has the largest value for all the four centrality metrics.

Table 6. Spearman's rank-based correlation coefficient among the Centrality metrics

	EVC	BWC	CIC
DegC	0.80	0.87	0.75
EVC		0.52	0.80
BWC			0.68

FUTURE RESEARCH DIRECTIONS

Very few works have been conducted on network graphs related to the US. We review these works below: E. A. Fogarty et al (2008) conducted a network analysis-based study on the hurricanes that made landfalls in the US from 1851 to 2008. A set of 23 non-overlapping regions (nodes) of the US that were affected with at least one hurricane were identified; two nodes were linked with an edge if at least one hurricane impacted the regions corresponding to both of them. The centrality metrics were extensively used in this study to estimate the connectivity of the regions. One of the interesting conclusions from this study was that regions (like Louisiana) with a high occurrence rate of hurricanes had a low connectivity with the rest of the regions; on the other hand, regions with high connectivity (like Virginia) had a low occurrence rate.

Lin et al (2014) conducted a network analysis of food flows within the US and had the following results: The distributions for the degree centrality and betweenness centrality were observed to be normal and Weibull (Balakrishnan & Nevzorov, 2003) in nature. A power-law relationship (Balakrishnan & Nevzorov, 2003) existed between the degree centrality and betweenness centrality metrics, indicating a vulnerability to the disturbance of key nodes. A. Lyte et al (2015) conducted a citation network-based analysis of the different sections that fall under the 52 titles of United States Code; each section is a node and there exists a directed edge from one section to another section if the former cites the latter. The betweenness and eigenvector centrality metrics were used in this study to identify major pathways of references from one section to another. The modularity-based Louvain community detection algorithm (Blondel et. al., 2008) was used to identify communities of sections that had similarities with respect to concepts and codes. It was observed that though sections under two or more related titles formed a single community, most of the communities

detected were a collection of sections under a particular title.

Cheung and Gunes (2012) conducted a complex network analysis study of the US air transportation network as of 2011 and compared it with the networks that existed in 1991 and 2001. Their study revealed no major changes in the features (like centrality and connectivity of the airports) of the air transportation networks that evolved with time (with increase in the number of airports and flight connections). A critical finding from the study was that the US air transportation network of 2011 has been identified to be more vulnerable to airport closures than it was in the past. The degree distribution of the 2011 US air transportation network only follows a partial Power-law (i.e., the distribution exhibited Power-law only after a degree value > 1), unlike the world-wide air transportation network that follows Power-law starting from degree value of 1 (Guimera et. al., 2005).

CONCLUSION

Our high-level contribution in this chapter is to illustrate centrality analysis of a connected graph of the states within a country. We implemented the algorithms to compute the centrality metrics and ran them on the US States network graph. The state of Missouri is the top-ranked node with respect to all the commonly studied centrality metrics such as degree, betweenness, closeness and eigenvector centralities. The states of Tennessee and Kentucky are in the top 2-3 rankings for at least two of the four centrality metrics. The state of Maine has the lowest ranking with respect to all the four centrality metrics, attributed to its location in the northeast corner of the country and with only one neighboring state in the US. The degree distribution appears to mimic a bi-modal Poisson distribution, while the betweenness centrality (BWC) exhibits a Power-law style distribution. The eigenvector and closeness centralities also exhibit

a Poisson-style distribution. The spectral radius ratio for node degree is 1.24 (moderately high for a Poisson network, vindicating the bi-modal degree distribution of the vertices). The approach taken in this chapter could be used to identify the most central states within a country and use this information to design the road/rail transportation networks. For countries with a reasonably larger area and an appreciable number of states, each state (except those in the corners of the country) typically shares border with a similar number of states. Hence, we anticipate the distribution of values for the node-level centrality metrics to be about the same for several other countries too. We thus opine the chapter to serve as a model for anyone interested in analyzing a connected graph of the states within a country from the perspective of node centrality.

KEY TERMS AND DEFINITIONS

Betweenness Centrality: A measure of the number of shortest paths that go through the node between any two vertices in the network.

Centrality: A quantitative measure of the importance of the node on the basis of the topological structure of the network.

Closeness Centrality: A measure of the number of hops of the shortest paths from the node to every other node in the network.

Correlation Coefficient: A measure of the statistical relationship between two or more datasets.

Degree Centrality: A measure of the number of neighbor nodes for the node.

Eigenvector Centrality: A measure of the number of neighbors of the node as well as the degree centrality of the neighbor nodes.

Context-Aware Approach for Restaurant Recommender Systems

D**Haoxian Feng***University of Ottawa, Canada***Thomas Tran***University of Ottawa, Canada*

INTRODUCTION

A recommender system provides online consumers with product information and recommendations through online e-business website to in order to enhance customers' shopping intention and improve the customers' shopping experience. In the specific area of restaurant recommendations, recommender systems aim to find the best restaurant that meets a user's need such as food type, environment type and so on.

The Chicago Restaurants Union has been using a FindMe type (Burke, Hammond, & Yound, 1997) recommender system called Entrée, which is used to recommend restaurants to the customers. This recommender system makes use of a typical recommendation algorithm based on knowledge (Sarwar, Karypis, Konstan, & Riedl, 2001, pp.285-295), which only uses the online operations of users as a basis, and is therefore lack of using historical data of users. This paper uses a context-aware approach to consider users' historical data for recommender systems that provide suggestions for restaurants.

The rest of this paper is organized as follows: Section 2 provides background information restaurant recommender systems. Section 3 presents the recommender algorithms used in our experiments. Section 4 describes the Entrée dataset; present data scrubbing process and the user behavior mining on this dataset; report the experimental results. Section 5 discusses the value of the results, their potential applications, and challenges and weak-

nesses. Section 6 concludes the paper and proposes some future research directions.

BACKGROUND AND RELATED WORK

Upsurge of Recommender Systems

In the 90s of the last century, the field of electronic commerce began to flourish and personalized recommender system also rose its first wave. Some large e-commerce sites such as Amazon launched their own personalized recommender system. Literature reported that 35 percent of Amazon's incremental sales came from their recommender system (Figiel, Epstein, McDonald, 1998, pp.20-25). At the same time, a sensational paper published by Amazon in 2000, entitled "Item-based collaborative filtering recommendation algorithms" (Sarwar, et al., 2001), has become one of the most famous literature in this area. Ever since then, personalized recommendation technology has become an irresistible trend.

Restaurant Recommender System: The Entrée System

As mentioned above, in the era of the Internet economy, recommender systems have been widely used in various business areas, which also include food industry. Burke (1999) stated the restaurant recommender system, Entrée, "makes its recom-

DOI: 10.4018/978-1-5225-2255-3.ch153

mentations by finding restaurants in a new city similar to restaurants the user knows and likes” (p.69).

Entrée is a recommender system using FindMe approach to assist users browsing which allows users to navigate by stating their preferences with respect to a given restaurant, thereby refining their search criteria.

When using this system, firstly a user needs to submit an “entry point” which is a known restaurant. (Or, the system will give a default “entry point” for new users.) Then the system offers a range of criteria, and according to the criteria chosen by the user, it will display a few restaurants that meet the users’ need. At the same time, the user would set their preferences until an acceptable restaurant is recommended.

As shown in Figure 1, the Entrée system finds a restaurant called “BrauhoF” that is similar to a restaurant called “Biergasthof” that the user used to choose. Then, if the user wants to find one that is similar to ” BrauhoF ” but slightly cheaper, she can click the “Less \$\$” button. Figure 2 shows the result of such action. In the same way, the user can choose cheaper, nicer or more traditional restaurants by clicking the corresponding buttons. The system will refresh the recommendation results based on the user’s operation, and finally help her to find the restaurant she desires.

The recommendation technology that Entrée use is knowledge-based similarity search. There are two basic search modes: one is based on the similarity retrieval, and the other is based on users’ evaluation result. When finding some similar

Figure 1. Entrée: A FindMe type system (Jannach, Zanker, Felfernig, & Friedrich, G. 2010)

Figure 2. Entrée: A FindMe type system (Jannach et al., 2010)

restaurants, the user selects in a given item directory, and requests for other similar items.

However, this traditional recommender system only uses the online operations of the users as a basis with just a few options like cheaper, quieter, etc. So, it is far from meeting the real needs of users. The main reason for this problem is the insufficient use of historical data of the users. Robin Burk and Hammond and Yound (1997) proposed the concept of hybrid recommendation models based on the original knowledge-based recommendation and designed an improved the Entrée system. He firstly mapped the navigation information of the Entrée system to a series of implicit ratings, and user-based collaborative filtering algorithm (Wang, De Vries, & Reinders, 2006) was then used to get the prediction score. It proved to achieve better results.

Related Work

Collaborative Filtering

A common approach for recommender systems is collaborative filtering (Breese, Heckerman, & Kadie, 1998). In general, it recommends the content that the users may be interested in according to the preference of the group sharing the same hobbies. Collaborative filtering analyzes the responses of users' preferences for goods and the main way to respond is rating or social filtering (Shardanand & Maes, 1995).

There are two very popular methods to compute the similarity measure $\text{sim}(u, u')$ between users in collaborative recommender systems. One is a correlation-based approach (Jannach et al., 2010):

$$sim(x, y) = \frac{\sum_{s \in S_{xy}} (r_{x,s} - \bar{r}_x)(r_{y,s} - \bar{r}_y)}{\sum_{s \in S_{xy}} (r_{x,s} - \bar{r}_x)^2 \sum_{s \in S_{xy}} (r_{y,s} - \bar{r}_y)^2} \quad (2.1)$$

where the $r_{x,s}$ and $r_{y,s}$ are the ratings of the items given by the user x and y , S_{xy} is the set of all items that rated both by the user x and y .

Another one is a cosine-based approach (Jan-nach et al., 2010):

$$sim(\vec{x}, \vec{y}) = \frac{\vec{x} \cdot \vec{y}}{|\vec{x}| * |\vec{y}|} \quad (2.2)$$

where the $\cdot$ means the dot product of vectors, $|\vec{x}|$ and $|\vec{y}|$ are the Euclidian length of the vectors.

There are also some specific calculations. For example, Oku and Nakajima and Miyazaki and Uemura (2006) proposed a context-aware SVM methods by using SVM to calculate the similarity between restaurants based on the context parameters of users' and characters of restaurants.

Sarwar et al. (2001) showed that item-based collaborative filtering can outperform the original user-based collaborative filtering.

Context-Aware Recommender Systems

This section discusses recommender systems based on context-aware (Foltz, P. W. 1990), which may consider the time, location or other factors when making recommendations. The traditional recommender system only considers two dimensions – users and items:

$$R : \text{User} * \text{Item} \rightarrow \text{Rating} \quad (2.3)$$

But context-aware recommender systems would take context information into account:

$$R : \text{User} * \text{Item} * \text{Context} \rightarrow \text{Rating} \quad (2.4)$$

There are 3 main methods in context-aware recommender systems:

1. Contextual pre-filtering, which selects only the information and data related to context for building recommender systems;
2. Contextual post-filtering, which filters the results of recommender system and retains only the results that contain contextual information; and
3. Contextual modeling, which uses contextual information directly in the recommendation algorithm.

The figure of the above methods is shown as Figure 3.

Contextual pre-filtering uses context information to filter when choosing the data for recommender system by using the current context-aware information to make a match.

Musto and Semeraro and Lops and de Gemmis (2013) extended the eVSM (enhanced vector space model) which is exactly a pre-filtering type context-aware recommendation.

Contextual post-filtering considers the contextual information only when the recommended item list is generated, then it will consider context information to filter out irrelevant items and adjust the order of items in the list. This process is illustrated in Figure 4.

Contextual post-filtering can be divided into two types, namely heuristic-based and model-based contextual post-filtering. Heuristic-based approach filters and changes the order according to some common characteristics of a user in the certain scenario. And model-based approach builds a model to estimate the probability that a user selects a certain item in a certain context.

Despite the fact that contextual pre-processing and contextual post-processing can be realized by the two-dimensional recommendation function, the contextual model can be extended

Figure 3. Paradigms for incorporating context in recommender systems: (a) Contextual pre-filtering; (b) contextual post-filtering; (c) contextual modeling (Abbar, Bouzeghoub, & Lopez, 2009)

Figure 4. Contextual post-filtering approach: recommendation list adjustment (Abbar et al., 2009)

to higher dimensional recommendation model. Lee and Teng (2007) proposed collaborative recommender with multi-criteria decision analysis with a dataset from Zagat. It considers multiple aspects of the restaurant include food, decor, service and price. Zhang et al. (2016) proposed a model that uses both implicit (e.g. demographic and geographic information) and explicit (e.g. ratings and reviews) preferences of users to make restaurant recommendations. For example, a lot of restaurant recommendation websites, such as Yelp, Zagat and Dianping, are using Location-Based Services to both website and mobile users.

PROPOSED APPROACH

Approach Overview

This paper builds a recommender system for which the underlying algorithm is the bias-based SVD algorithm, which is a matrix factorization algorithm enhanced with baseline predictors and stochastic gradient descent process. In the next section, the authors will compare the performance of the bias-based SVD algorithm with the item-based collaborative algorithm.

In the coming subsections, the authors are going to provide detailed descriptions of the item-based

collaborative filtering algorithm, as well as the algorithms involved in bias-based SVD method.

Item-Based Collaborative Filtering

The K-nearest neighbor algorithm (Horton & Nakai, 1997) is usually used in item-based collaborative filtering algorithm. It computes the similarity between the two items through the nearest adjacency matrix and then produces the predicted value for the user u using the weighted average approach. In addition, mechanisms like Pearson correlation, vector cosine similarity as (2.2), etc. can be added in this algorithm to improve the prediction result.

The advantage of this method is that it is easy to interpret the results, which is one of the most important features of the recommender system. But its shortcomings are also obvious: First, it needs user's score. Secondly, if the data is sparse, its performance will become poor.

This paper uses the Pearson correlation and obtains the prediction using similarity as a weight to calculate the weighted summation.

SVD- Singular Value Decomposition

Matrix Factorization

The mathematical foundation of the matrix factorization algorithm (Ma, Yang, Lyu, & King, 2008) is the transformation of matrices. They have $A = pEq = pq$, where A is a user-item rating matrix, E is a diagonal matrix, p can be viewed as the feature matrix of users, and q as the feature matrix of items (Koren, Bell, & Volinsky, 2009).

Readers can imagine that each line of the matrix represents a user and each column represents an item, and the numbers in cells represent the ratings of each item from each user. For example:

$$\begin{matrix} 5 & 2 & 4 & 4 & 3 & u_{11} & u_{12} & i_{11} & i_{12} & i_{13} \\ 3 & 1 & 2 & 4 & 1 & u_{21} & u_{22} & i_{21} & i_{22} & i_{23} \\ 2 & & 3 & 1 & 4 & u_{31} & u_{32} & i_{31} & i_{32} & i_{33} \end{matrix} \quad (2.5)$$

This is how matrix factorization works to deal with missing values in the matrix. The blank one is the missing value. Our goal is to find those two matrices on the right side by using existing ratings. More intuitively, researchers can also regard the rating matrix as the dot product of p and q as:

$$\widehat{r_{ui}} = p_u^T q_i \quad (2.6)$$

where the p_u^T and q_i are the same as p and q .

Baseline Predictors

Matrix factorization is using the hidden class to connect the users and items. But in some cases, the rating system has some inherent attributes of users and items while items or users also have some inherent attributes between each other. In order to settle this shortage, Koren (2009) proposed a baseline predictor to deal with this problem.

They set μ to be the mean value of all the ratings of the training set. They use b_i and b_u to represent the preference of items and users and $\widehat{r_{ui}}$ represent the predict rating of user u for item i . In particular, b_u represents the rating tendency of user that some users prefer to rate higher while some do not. b_i represents the rated pattern of the particular item in the dataset.

$$\widehat{r_{ui}} = \mu + b_i + b_u \quad (2.7)$$

These two parameters can be calculated as an optimization problem such as the least square procedure:

$$\min_{b^*} \sum_{(u,i) \in \mathbb{R}} (r_{ui} - \mu - b_i - b_u)^2 + \lambda_1 (\sum_u b_u^2 + \sum_i b_i^2) \quad (2.8)$$

where b^* represents all biases including user and item, r_{ui} represent the observed rating of user u for item i and $R(i)$ or $R(u)$ represent the whole set of item or user. The first term, the regulariza-

tion parameter, λ_1 , avoids overfitting by penalizing the magnitudes of the parameters (Koren 2009).

Bias-Based SVD

In this paper, the authors use SVD with baseline predictor, which is the combination of matrix factorization and baseline predictors. The authors call it bias-based SVD.

As an evolution of equation 2.6 and the matrix factorization methods, the rating model can be improved as (Koren et al., 2009):

$$\hat{r}_{ui} = \mu + b_i + b_u + p_u^T q_i \quad (2.9)$$

In this case, researchers use this loss function:

$$\min_{b^+, q^+, p^+} \sum_{(u,i) \in \mathbb{R}} (r_{ui} - \mu - b_i - b_u - p_u^T q_i)^2 + \lambda_2 (\sum_u b_u^2 + \sum_i b_i^2 + \|q_i\|^2 + \|p_u\|^2) \quad (2.10)$$

$\lambda_2 (\sum_u b_u^2 + \sum_i b_i^2 + \|q_i\|^2 + \|p_u\|^2)$ is the penalty term.

And researchers use stochastic gradient descent to optimize equations 2.11 - 2.14:

$$b_i \leftarrow b_i + \gamma(e_{ui} - \lambda_2 * b_i) \quad (2.11)$$

$$b_u \leftarrow b_u + \gamma(e_{ui} - \lambda_2 * b_u) \quad (2.12)$$

$$q_i \leftarrow q_i + \gamma(e_{ui} * p_u - \lambda_2 * q_i) \quad (2.13)$$

$$p_u \leftarrow p_u + \gamma(e_{ui} * q_i - \lambda_2 * p_u) \quad (2.14)$$

where those four parameters need to be pushed forward along the steepest descent direction. γ is learning rate which needs to be chosen according to the experiment. The stochastic gradient descent algorithm is the basic optimization algorithm in optimization theory. It finds the steepest descent direction by the partial derivative of the parameter.

Then the authors have the error formula as 2.15:

$$e_{ui} = r_{ui} - \hat{r}_{ui} = r_{ui} - p_u^T q_i = r_{ui} - \sum_{k=1}^k p_{uk} q_{ki} \quad (2.15)$$

EXPERIMENT AND EVALUATION

Dataset

In this paper, the authors use the Entrée dataset. The researchers collected the data of user behaviors from September 1996 to April 1999 and organized them according to year quarter (Q). Specifically, in Q3 1996 and Q2 1999 each contains only one month. This dataset tagged 9 users' behavior records (UC Irvine Machine Learning Repository, 2000) from L to T, representing the following information respectively [Burke et al., 1997; Breese et al., 1998]:

{ 'Browse', 'Entry Point', 'End Point', 'Nicer', 'More Traditional,' 'More Creative', 'Cheaper', 'Livelier', 'Quieter', 'Change Cuisine' }.

The original dataset looks like the website log. It documents every click of the users. Each line in the dataset represents a session of a user's interaction with the system. The (tab-separated) fields are as follows:

Date, IP, Entry point, Rated restaurant1,..., Rated restaurantN, Endpoint

The dataset has a total of 50672 lines like the line above.

User Behavior Mining

To better understand the model, the researchers consider the semantic information as some specific ratings (Yu, Nakamura, Jang, Kajita, S., & Mase, 2007; Foltz, 1990) include both explicit evaluation (Carroll & Swain, 1993) and implicit evaluation (Joachims, Granka, Pan, Hembrooke, & Gay, 2005).

Explicit Behavior

1. The content that users are interested in:
 - a. Here, Entry Point is entered by the user, then the system will recommend some restaurants similar to the Entry Point restaurant, according to the characteristics of this restaurant. It is very likely that the user will choose their most ideal restaurant as the standard to find similar candidates. Therefore, for this kind of restaurant, the authors use a function $X(u, r) = 1$ to express the strongest interest rate.
2. The content that users are not interested in:
 - a. For evaluations such as 'Nicer', 'More Traditional', 'More Creative', 'Cheaper', 'Livelier', 'Quieter', 'Change Cuisine', which states that the users do not like the restaurant, and the restaurant will not be their ideal candidate at least for a long period. Therefore, authors score them as $X(u, r) = -1$, which represents a strong discomfort.

Table 1. Behavior-Score mapping

Behaviors	Scores
Browse	-0.5
Change Cuisine	-1
Cheaper	-1
Nicer	-1
More Creative	-1
More Traditional	-1
Livelier	-1
Quieter	-1
Entry Point	1
End Point	0.8

Implicit Behavior

For Exit Point, the user would confirm the end of the search on this "exit" (for some users that directly log out without confirming the Exit Point, the system will not record this value). If there is an Exit Point, the authors consider that the user is very likely to choose this restaurant. But this is not for sure because they may just follow the ending process. Therefore, for such implicit behavior, the authors can only give $X(u, r) = 0.8$, assuming that the user is very likely to choose this kind of restaurant.

For another behavior, 'Browse', while users do not give the restaurant a negative evaluation directly, they do not seem to choose this kind of restaurant eventually. Therefore, authors give $X(u, r) = -0.5$.

The authors summarize these points in Table 1.

After finishing the behavior-score mapping process authors have Table 2.

Table 2. Original dataset

User	Restaurants	Positive Ratings	Negative Ratings
22396	1149	50583	189291

Data Scrubbing and Pre-processing

The data are recorded over 20,000 users' information, many of which are too sparse, for example, some users browsed very quickly and departed directly in a few minutes. Therefore, the authors need to preprocess the data properly:

1. The number of evaluation restaurants of our users must be more than 15 so that the authors can have a less sparse rating matrix and make sure every user is in the rating matrix have enough information for recommender systems.
2. Users may use the system many times in a short period. So, the authors consider the same user in different quarters as different users.
3. Users may rate the same restaurant many times. The authors documented every time of it and calculated the sum of all the ratings of each user. The authors set the rating to be 1 if the calculated sum is larger than 1 and set the rating to be -1 if the calculated sum is smaller than -1. As such, the authors make use of every single rating of the users to make a better prediction.
4. In order to fit in the algorithm, the authors move the range of the ratings (-1,1) to (1,3) by adding 2 points to each rating.
5. For restaurants, researchers require at least three users have been evaluated it. Because some users have been removed in step 1, the number of restaurants will have to be reduced.

After the preprocessing, the information of our dataset is shown in Table 3.

Table 3. Dataset after pre-processing

User	Restaurants	Positive Ratings (2,3)	Negative Ratings (1,2)
4089	672	15975	64245

Results and Evaluation

Evaluation Metrics

MAE, standing for Mean Absolute Error, is a measurement to measure how close the predictions are to the real value.

$$MAE = \frac{\sum_{u,i \in T} |r_{ui} - \hat{r}_{ui}|}{|T|}$$

RMSE, Root-Mean-Square Error, is a measurement to the square root of the ratio of the difference between observed value and the true value and the observation times.

$$RMSE = \sqrt{\frac{\sum_{u,i \in T} |r_{ui} - \hat{r}_{ui}|^2}{|T|}}$$

In the above two formulas, u represent users, i represent items, r_{ui} represents the rating of an item i from the user u , and $\hat{r}_{ui}$ represents the predicted rating calculated by the recommender system.

They are both accuracy measurements and scale-dependent which cannot be used to make comparisons between series that are on different scales (Hyndman & Athanasopoulos, 2014).

Mean absolute error weights all individual differences equally while root mean squared error gives relatively high weight to large errors and punishes large errors more severely.

Table 4. Errors of various iteration times

Iterations	1	5	10	15	20	25
RMSE	0.578135	0.56587	0.560847	0.557987	0.556211	0.555176
MAE	0.431502	0.422098	0.41853	0.416308	0.415167	0.414898
Iterations	30	35	40	45	50	
RMSE	0.554555	0.554171	0.553933	0.553794	0.553711	
MAE	0.413728	0.413546	0.413543	0.413324	0.413243	

Process and Results

The authors run the dataset after pre-processing on both the item-based collaborative filtering algorithm and the bias-based SVD algorithm, and separate the training set and the test set in ratio 8:1.

In order to find an appropriate iteration time for the bias-based SVD algorithm, the authors have done some pre-training (see Table 4).

In Figure 5, the x-axis represents the iteration times, and the y-axis represents the test set's RMSE and MAE value. The RMSE and MAE values have a significant drop at iteration times $k = 5$ then starts to decay much more gently. And both of them almost convergence when k is larger than 20. Hence, the authors chose 20 as the iteration times for the next SVD experiments.

The authors train the item-based and SVD model for each quarter and the whole data set.

Table 5. RMSE and MAE value of the whole test dataset

	Item-Base	Bias-Based SVD
RMSE	0.615462	0.587139
MAE	0.461834	0.438032

Finally, the authors obtain the RMSE and MAE values as follows:

It can be seen in Table 5 that the bias-based SVD algorithm outperforms the item-based collaborative filtering one in both evaluation criteria: 4.6% in RMSE and 5.2% in MAE. These are the results that the authors hoped for. Note that the dataset has a lot of missing values, which significantly affect the correlation calculation. Although the data scrubbing process set a threshold of 15 ratings per user, there are still a lot of missing

Figure 5. Error-Steps values line chart

Figure 6. RMSE value for two different models

values in the dataset. But the bias-based SVD method can fulfill all those missing values and help with the prediction.

Also, the authors compare each quarter of year's performance from Figures 6 and 7.

As shown in Figure 6 and Figure 7, the RMSE values show that bias-based SVD outperforms the item-based collaborative filtering method in every quarter, except only for the third quarter in 1996. This shows that bias-based SVD algorithm has stronger capabilities to deal with missing values.

Also, both methods show the relatively high quality of prediction. Thus, using the transformation from the user behaviors to ratings, researchers

can empower those classical recommendation algorithms to achieve good results.

DISCUSSION

Bias-based SVD methods had a great success in Netflix Prize on the movie or video recommendation systems. And it now turns out to have very good performance in this restaurant dataset.

It is encouraging to learn that the bias-based SVD method achieves very good performance on the Entrée dataset after all those data preprocessing steps. Actually, this kind of transformation from

Figure 7. MAE value for two different models

user behaviors to ratings can be used in different domains. For example, in the music recommendation domain, developers can use a tag system to allow users to tag the music they heard. Those tags can form the context of the music dataset to which the process described in this paper can be re-applied. Also, this method can be used in web browsing record-based recommendation systems.

But since the Entrée system is a knowledge-based system originally, the transformation from user behaviors to ratings is based on the assumption by the researchers, which may not reflect user personal preferences precisely. This is because there are some opposite behaviors among all the behaviors, such as ‘nicer’ with ‘cheaper’ etc., which can weaken the relation or the opposition between the behaviors.

CONCLUSION

The internet is changing the way of people’s thinking, their habits of life and the relationship between them, and is building unprecedented business and social models. Our information is growing in geometric exponential level, but our ability to obtain information remains the same as our ancestors’. The information explosion has made our life comfortable but also created heavy work for us to find the things we want. The emergence of recommender systems meets our need in this new era.

This paper uses a bias-based SVD method for restaurant recommendations and compares it with the traditional item-based collaborative filtering algorithm, both operating on the Entrée dataset after some pre-processing steps. The authors consider different user behaviors and transform them into ratings, which are then fed as input into the recommender systems. The results show that the bias-based SVD method outperforms the item-based collaborative filtering algorithm although both methods attain relatively high prediction quality thanks to the behavior-score mapping and pre-processing.

FUTURE RESEARCH DIRECTIONS

As mentioned in the Discussion section, a shortcoming of our approach is in the context-aware process. In the future, the authors can take the opposite user behaviors into account. The authors find that “Nicer”/ “Cheaper”, “Livelier”/ “Quieter”, “more Traditional”/ “more Creative” are opposite to each other. Considering those behaviors in pairs may lead to a better result. The authors can also use the characteristic of restaurants to help build a better dataset to represent the preferences of users. In addition, the authors can use Bayesian Personalized Ranking (Rendle, Freudenthaler, Gantner, & Schmidt-Thieme, 2009) to improve the process of implicit information. Also, the authors plan to look into alternative methods for better evaluating the value of our proposed approach in the context of related works.

KEY TERMS AND DEFINITIONS

Baseline Predictors: A method that considers the user bias, the item bias and the global average of ratings in the dataset to provide better recommendation results.

Behavior-Score Mapping: A transformation process from the behavior to the ratings under some rules.

Context-Aware Recommender System: A recommender system that considers not only the ratings but also includes other information such as time, emotion and so on.

Gradient Descent: A fundamental optimization algorithm that is used to find the steepest descent direction and the local minimum.

Item-Based Collaborative Filtering: A classical and most widely used recommendation algorithm that uses the similarities between items.

Matrix Factorization: A way to decompose a matrix to the product of several matrices.

Singular Value Decomposition (SVD): One of the matrix factorization methods to decompose a matrix to the product of two orthogonal matrices and one diagonal matrix.

D

Data-Centric Benchmarking

Jérôme Darmont

Université de Lyon, Lyon 2, ERIC EA3083, France

INTRODUCTION

In data management, both system designers and users casually resort to performance evaluation. On one hand, designers need to test architectural features and hypotheses regarding the actual (vs. theoretical) behavior of a system, especially in terms of response and scalability. Performance tuning also necessitates accurate performance evaluation. On the other hand, users are also keen on comparing the efficiency of different technologies before selecting a software solution. Thence, performance measurement tools are of premium importance in the data management domain.

Performance evaluation by experimentation on a real system is generally referred to as benchmarking. It consists in performing a series of tests on a given system to estimate its performance in a given setting. Typically, a data-centric benchmark is constituted of two main elements: a data model (conceptual schema and extension) and a workload model (set of read and write operations) to apply on this dataset, with respect to a predefined protocol. Both models may be parameterized. Most benchmarks also include a set of simple or composite performance metrics such as response time, throughput, number of input/output operations, disk or memory usage, etc.

The Transaction Processing Performance Council (TPC), a non-profit organization founded in 1988, plays a preponderant role in data-centric benchmarking. Its mission is to issue standard benchmarks, to verify their correct application by the industry, and to publish performance test results. TPC members include all the major industrial actors from the database field.

The aim of this chapter is to present an overview of the major past and present state-of-the-art

data-centric benchmarks. Our review includes the TPC standard benchmarks, but also alternative or more specialized benchmarks. We survey benchmarks from three families: transaction benchmarks aimed at On-Line Transaction Processing (OLTP), decision-support benchmarks aimed at On-Line Analysis Processing (OLAP) and big data benchmarks. Eventually, we discuss the issues, tradeoffs and future trends in data-centric benchmarking.

BACKGROUND

Transaction Processing Benchmarks

The first TPC benchmark for relational, transactional databases, TPC-C (TPC, 2010), has been in use since 1992. TPC-C features a complex business database (a classical customer-order-product-supplier model with nine types of tables bearing various structures and sizes) and a workload of diversely complex transactions that are executed concurrently. The performance metric in TPC-C is transaction throughput. As all TPC benchmarks, TPC-C's only parameter is a scale factor SF that determines data size. TPC-C was complemented in 2007 by TPC-E (TPC, 2015a), which simulates a brokerage firm with the aim of being representative of more modern OLTP systems. In its principles and features, TPC-E is otherwise very similar to TPC-C.

There are few alternatives to TPC-C and TPC-E for relational applications. Yet, some benchmarks fit niches where there is no standard benchmark. For instance, OO7 (Carey et al., 1993) and OCB (Darmont & Schneider, 2000) are object-oriented database benchmarks modeling engineering applications, e.g., computer-aided design or software

DOI: 10.4018/978-1-5225-2255-3.ch154

engineering. However, their complexity makes both these benchmarks hard to understand and implement. Moreover, with objects in databases being more commonly managed in object-relational systems nowadays, object-relational benchmarks such as BUCKY (Carey et al., 1997) and BORD (Lee et al., 2000) now seem more relevant. Such benchmarks focus on queries implying object identifiers, inheritance, joins, class and object references, multivalued attributes, query un-nesting, object methods, and abstract data types. However, typical object navigation is considered already addressed by object-oriented benchmarks and is not taken into account. Moreover, object-relational database benchmarks have not evolved since the early 2000's, whereas object-relational database systems have.

Similarly, XML benchmarks aim at comparing the various XML storage and querying solutions developed since the late nineties. From the early so-called XML application benchmarks that implement a mixed XML database that is either data-oriented (structured data) or document-oriented (in general, random texts built from a dictionary), XBench (Yao et al., 2004) stands out. XBench is indeed the only benchmark proposing a true mixed dataset (i.e., data *and* document-oriented) and helping evaluate all the functionalities offered by XQuery. FlexBench (Vranec & Mlýnková, 2009) also tests a large set of data characteristics and proposes query templates that allow modeling multiple types of applications. Finally, Schmidt et al. (2009) and Zhang et al. (2011) propose benchmarks that are specifically tailored for testing logical XML model-based systems, namely native XML and XML-relational database management systems, respectively.

Decision-Support Benchmarks

TPC-H (TPC, 2014a) has long been the only standard decision-support benchmark. It exploits a classical product-order-supplier database schema, as well as a workload that is constituted of twenty-two SQL-92, parameterized, decision-support

queries and two refreshing functions that insert tuples into and delete tuples from the database. Query parameters are randomly instantiated following a uniform law. Three primary metrics describe performance in terms of power, throughput, and a combination of power and throughput.

However, TPC-H's database schema is not a star-like multidimensional schema that is typical in data warehouses. Furthermore, its workload does not include any true OLAP query. TPC-DS (TPC, 2015b) now fills in this gap. Its schema represents the decision-support functions of a retailer under the form of a constellation schema with several fact tables and shared dimensions. TPC-DS' workload is constituted of four classes of queries: reporting queries, ad-hoc decision-support queries, interactive OLAP queries, and extraction queries. SQL-99 query templates help randomly generate a set of about five hundred queries, following non-uniform distributions. TPC-DS features one primary throughput metric that takes both query execution and data warehouse maintenance into account.

Given the primordial importance of data integration in many data-centric (including data warehousing) scenarios, TPC-H was recently complemented by TPC-DI (TPC, 2014b). TPC-DI focuses on Extract, Load and Transform (ETL) processes. Data are first generated in a staging area as if they were extracted from a virtual retail brokerage firm's operational databases. Then, data are transformed through, e.g., type conversions, attribute splits or merges, and error checks. Finally, data are loaded into a warehouse constituted of five fact tables and eight dimension tables. There are two load phases: an initial, so-called historical load, and then incremental updates. Transformations are different in these two phases. TPC-DI's main metric is a combination of throughputs from the historical load and two incremental updates.

There are, again, few decision-support benchmarks out of the TPC, but with TPC-DS having had an eight-year long development, alternative data warehouse benchmarks were proposed. Published by the OLAP council, a now inactive

organization founded by OLAP vendors, APB-1 (OLAP Council, 1998) was the first of them and actually predates TPC-DS. APB-1 has been intensively used in the late nineties. However, APB-1 is very simple and rapidly proved limited to evaluate the specificities of various activities and functions. Thus, more elaborate alternatives were proposed, such as DWEB (Darmont et al., 2007), which can be parameterized to generate various ad-hoc synthetic data warehouses and workloads that include typical OLAP queries, and SSB (O'Neil et al., 2009), which is based on TPC-H's database remodeled as a star schema and features a query workload that provides both functional and selectivity coverage.

It is also worth noting that TPC-DS is a complex benchmark. Thence, simpler benchmarks are still in use, especially for testing OLAP scenarios in the cloud. For instance, TPC-H was used to benchmark Hadoop and Pig (Moussa, 2012) and SSB for testing the efficiency of view materialization in the cloud (Perriot et al., 2014). Niche benchmarks also rely a lot on TPC-H. XWeB (Mahboubi & Darmont, 2010) proposes a unified reference model for XML warehouses and its associate XQuery decision-support workload. RTDW-bench (Jedrzejczak et al., 2012) is designed for testing the ability of a real-time data warehouse to handle a transaction stream without delay, given an arrival rate. Eventually, Bär and Golab (2012) propose a benchmark for stream data warehouses that measures the freshness of materialized views.

Finally, a couple of benchmarks are even more specific (and unrelated from TPC-H), e.g., Spadawan (Lopes Siqueira et al., 2010), which allows performance evaluation of specific, complex operations in spatial data warehouses, and BenchDW (Triplet & Butler, 2013), which targets biological data warehouses and particularly focuses on performance metrics, with twenty-two different metrics such as documentation quality, accuracy and response time.

Big Data Benchmarks

In the timely trend of big data analytics, benchmarking needs are as high as ever to compare alternative systems, including the many NoSQL database systems. In this context of data variety, volume and velocity, adaptability and scalability are premium features that must be evaluated. The TPC promotes two benchmarks for big data. TPC-VMS (TPC, 2013) is actually a benchmarking environment for virtualized databases that allows running TPC-C, TPC-E, TPC-H or TPC-DS on three virtual machines (VMs). Its metric is the minimum value of the selected benchmark's metric on all VMs. TPCx-HS (TPC, 2015c) focuses on Hadoop and MapReduce-based applications. It models a simple application (with no data model directly available) and features, in addition to classical metrics, availability and energy metrics.

Before the TPC could issue its big data benchmarks, and still in parallel, there are many industrial and academic initiatives. MalStone (Open Cloud Consortium, 2009) is a benchmark for assessing data intensive parallel processing. It features MalGen, a synthetic data generator that produces large datasets generated probabilistically following specified distributions. In the same line, HiBench (Huang et al., 2010) is a set of Hadoop programs, ranging from data sorting to clustering, aimed at measuring metrics such as response time, HDFS bandwidth consumption and data access patterns. SWIM (Chen et al., 2013) also measures the performance of Hadoop/MapReduce systems. SWIM contains suites of workloads of thousands of jobs, with complex data, arrival, and computation patterns, and therefore provides workload-specific optimizations. Finally, HcBench (Saletore et al., 2013) models real Hadoop usages in a datacenter. HcBench features various job types and data sizes.

By contrast, YCSB (Cooper et al., 2010) is a framework that focuses on data, and more specifically on performance evaluation of key-

value stores. YCSB defines several metrics and workloads to measure system behavior in different situations, or the same system when using different configurations. OLTP-Bench (Curino et al., 2012) is the first true benchmarking framework designed for cloud transactional database systems as a service. OLTP-Bench actually features a set of existing micro-benchmarks (i.e., designed to test one very specific aspect of performance, e.g., ResourceStresser), popular benchmarks (e.g., TPC-C) and real-world applications (e.g., Wikipedia).

Regarding big data analytics, PRIMEBALL (Ferrarons et al., 2013) aims at providing a real-life context to cloud data warehouse benchmarking. Its authors provide the specifications of a fictitious news site hosted in the cloud that is to be managed by the framework under analysis, together with several objective use cases and measures for evaluating system performance. The Big Data Benchmark (Amplab, 2014) goes one step further by actually implementing existing analytical workload models by Pavlo et al. (2009). Its only metric is the response time of such relational queries as scans, aggregations and joins. It can be used for both MapReduce-based systems (such as Shark and Hive) and classical parallel database systems. BigBench (Rabl et al., 2015) is a so-called a specification-based benchmark that is independent from technology. BigBench relies a lot on TPC-DS, borrowing its data model and part of its workload model. The remainder of the workload is adapted from big data use cases issued by the McKinsey Global Institute. Finally, yet other benchmarks, i.e., CloudSuite (Yasin et al., 2014) and DCBench (Jia et al., 2013), feature machine learning and data mining-oriented workload models that mostly run on Hadoop and exploit the Mahout library.

Eventually, BigDataBench (Wang et al., 2014) aims at providing the widest possible scope of big data models and workloads. It includes nineteen benchmarks representing a large variety of data models, workload models and application scenarios from search engines, social networks,

e-commerce, multimedia analytics and bioinformatics. Workload models cover OLTP, “cloud OLTP” and OLAP. As BigBench, BigDataBench also allows alternative implementations, e.g., using MapReduce or Spark.

ISSUES AND TRADEOFFS IN DATA PROCESSING BENCHMARKS

Gray (1993) defines four primary criteria to specify a “good” benchmark.

1. **Relevance:** The benchmark must deal with aspects of performance that appeal to the largest number of potential users.
2. **Portability:** The benchmark must be reusable to test the performances of different DBMSs.
3. **Simplicity:** The benchmark must be feasible and must not require too many resources.
4. **Scalability:** The benchmark must adapt to small or large computer architectures.

In their majority, existing benchmarks aim at comparing the performances of different systems in given experimental conditions. This helps vendors position their products relatively to their competitors’, and users achieve strategic and costly software choices based on objective information. These benchmarks invariably present fixed data and workload models. Gray’s scalability factor is achieved through a reduced number of parameters that mainly allows varying database size in predetermined proportions. All TPC benchmarks notably feature a single scale factor parameter.

This solution is simple (still according to Gray’s criteria), but the relevance of such benchmarks is inevitably reduced to the test cases that are explicitly modeled. For instance, the typical customer-order-product-supplier data model from TPC benchmarks is unsuitable to many application domains. This leads benchmark users to design more or less elaborate variants of standard tools, when they feel these are not generic enough to

fulfill particular needs. Such users are generally not confronted to software choices, but to architectural choices or performance optimization tradeoffs within a given system or family of systems. In this context, it is essential to multiply experiments and test cases, and a monolithic benchmark is of reduced relevance.

To enhance the relevance of benchmarks aimed at system designers, three solutions are possible. The first one is to design an ad-hoc benchmark for a particular application, e.g., RTW-bench, Spadawan and BenchDW, for real-time, spatial and biological data warehouses, respectively. However, the benchmark's application span is necessarily quite narrow. One alternative is to resort to benchmark generators, also called tunable or generic benchmarks, such as OCB, DWEB or FlexBench, which help generate various data or workload models, and thus allow experiments to run in various conditions. The other alternative, which is preferred in recent benchmarks such as YSCB, OLTP-Bench and BigDataBench, is to offer a unifying framework that includes a comprehensive set of state-of-the-art benchmarks. However, the two latter approaches are mechanically detrimental to simplicity, which is a primordial criterion. It is thus necessary to devise benchmark suites that do not sacrifice simplicity too much.

FUTURE RESEARCH DIRECTIONS

The previous section showed that classical transaction and decision-oriented benchmarks are well established. However, big data benchmarking, which predominantly uses cloud technologies, faces a new paradigm and must measure new features. Thus, in addition to Gray's (1993) criteria for building a good benchmark, Folkerts et al. (2012) propose that the quality criteria that are commonly accepted by the benchmarking community must be revisited.

Although the cloud inherits from a long legacy of distributed systems, important issues are unique

to the cloud. For instance, the concept of elasticity applied to data management may translate in the ability to bring in new data sources dynamically to meet emerging needs (Pedersen, 2010). Thus, cloud benchmark data models should be dynamic. Moreover, the three or four Vs (if we include veracity) of big data are unequally addressed in current benchmarks, which mostly focus on scaling (volume) and, to a lesser extent, on variety with multi-benchmark suites such as BigDataBench. Among recent benchmarks, only HcBench features inter-job arrival rates that can simulate data streams. Yet, it is a quite low-level benchmark. Thus, RTDW-Bench and Bär and Golab's (2012) stream warehouse benchmark could be welcome additions in multi-benchmark suites.

With respect to veracity, specific security issues appeared in the new framework of the cloud, e.g., cloud provider or subcontractor espionage, cost-effective defense of availability or uncontrolled mashups (Chow et al., 2009). Such features are important to assess, for security is one of the top concern of cloud users and would-be users. Data consistency is also a concern, e.g., PRIMEBALL's metrics do not only target transaction performance and storage costs, but also data consistency. Bermbach et al. (2013) further advocate for a standard comprehensive benchmark for quantifying the consistency guarantees of eventually consistent storage systems. Moreover, for web application-based benchmarks, data quality assessment is also of premium importance. To the best of our knowledge, this intricate task has not been included yet in any big data benchmark.

Finally, the economic model of the cloud is fundamentally new. Instead of a costly initial investment, pay-as-you-go models allow users to pay a small amount per use, e.g., of a dataset, in return for a one-time advantage (Pedersen, 2010). Thus, cost is also a key criterion when benchmarking cloud/big data solutions. TPC benchmarks typically feature a cost metric, but it is presumably too high-level for fine-grained cost analyses.

CONCLUSION

Benchmarking is a small field, but it is nonetheless essential to data-centric research and industry. It serves both engineering and research purposes, when designing systems or validating solutions; as well as marketing purposes, when monitoring competition and comparing commercial products.

We subdivide benchmarks in three classes. First, standard, general-purpose benchmarks such as the TPC's do an excellent job in evaluating the global performance of systems. They are well suited to software selection by users and marketing battles by vendors, who try to demonstrate the superiority of their product at one moment in time. However, their relevance drops for some particular applications that exploit data or workload models that are radically different from those they implement. Ad-hoc benchmarks are a solution. They either are adaptations of general-purpose benchmarks, or specifically designed benchmarks. Designing myriads of narrow-band benchmarks is not time-efficient, though, and trust in yet another new benchmark might prove limited in the community. Hence, the last alternative is to use generic or multi-benchmarks that feature a common framework for generating various experimental possibilities. The drawback of this approach is that benchmark complexity must be mastered. In conclusion, before starting a benchmarking experiment, users' needs must be carefully assessed so that the right benchmark or benchmark class is selected, and test results are meaningful.

It is nonetheless clear that the TPC plays a primordial role in the data benchmarking community, not only by issuing standards, but also by structuring and leading the community, e.g., by organizing the annual Technology Conference on Performance Evaluation and Benchmarking (TPCTC). This event does not only promote the TPC's activity, but also greatly encourages industrial and academic advances in the field of performance evaluation and benchmarking, whether they are related to the TPC or TPC benchmarks or not.

KEY TERMS AND DEFINITIONS

Benchmark: A standard program that runs on different systems to provide an accurate measure of their performance.

Cloud Benchmarking: Use of cloud services in the respective (distributed) systems under test (Folkerts et al., 2012).

Database Benchmark: A benchmark specifically aimed at evaluating the performance of Database Management Systems (DBMSs) or DBMS components.

Data Model: In a data-centric benchmark, a database schema and a protocol for instantiating

this schema, *i.e.*, generating synthetic data or reusing real-life data.

Performance Metrics: Simple or composite metrics aimed at expressing the performance of a system.

Synthetic Benchmark: A benchmark in which the workload model is artificially generated, as opposed to a real-life workload.

Workload Model: In a data-centric benchmark, a set of predefined read and write operations or operation templates to apply on the benchmark's database, following a predefined protocol.

Data Linkage Discovery Applications

D

Richard S. Segall

Arkansas State University, USA

Shen Lu

University of South Florida, USA

INTRODUCTION

This chapter discusses the topic of linkage discovery for data and their applications. Since the publication of Segall and Lu (2014) which pertained to linkage discovery with glossaries many other investigators have performed research on applications of linkage discovery for big data under new conditions and criteria. This chapter enhances Segall & Lu (2014) by not only presenting a more coherent tabular summary of work of others presented in Segall & Lu (2014) and also again presented within this chapter, but also by including additional references that pertain to applications of linkage discovery not requiring a glossary framework.

BACKGROUND

This section discusses some of the terminology of text mining that is also used in linkage discovery that is web-based form of knowledge discovery. Latent Semantic Analysis (LSA) can be used to discover knowledge from text with a general mathematical learning method without knowing prior linguistic or perceptual similarity knowledge.

Latent Semantic Analysis (LSA) is a Natural Language Processing (NLP) technique that is based on similarity of words but not grammatical or syntactical structure and extracts knowledge through the similarity of individual words. The motivation of LSA in terms of psychology is that people learn knowledge only from similarity of

individual words taken as units, not with knowledge of their syntactical or grammatical function.

Experimental result for linkage discovery for glossaries was shown in Lu et al. (2011) and Lu et al. (2012) and by other investigators that, by combining glossaries with the text, we can extract more meaningful words from the text and then link similar sections together.

Latent Semantic Analysis (LSA) can provide the meanings of the terms based on the context. However, one article cannot include all of the domain knowledge and the definition extracted from the context where the term appears in that article is not accurate. But, in glossaries, all of the terms are defined clearly. In Lu et al. (2011) and Lu et al. (2012), we manually put the definitions of the terms in glossaries to those words in an article and use those definitions to improve the accuracy of the background knowledge we can extract from the context. In this way, we can define meaningful words and use them to decide the theme of the corresponding sections.

Ferret (2002) presented a method, called TOPICOLL, for using collocations for topic segmentation and link detection. Figure 1 below illustrates the automation of the algorithm of Ferret (2002) for detecting topic shifts.

TOPICOLL Algorithm [Source: Ferret (2002)]

Parameters:

1. State: {NewTopicDetection, InTopic, EndTopicDetection, OutOfTopic}
2. Sim: {True, False} // If

Figure 1. Automation for topic shift detection
[Ferret (2002)]

the context of the focus window and the context of the current segment is similar, Sim is True; otherwise, Sim is False.

```

3.      ConfirmNb: integer // the
        number of successive positions.
4.      Tconfirm: constant // the
        threshold of successive positions.
Input: Document
Begin:
Foreach FocusWindow is Document
{
1.      if(State == NewTopicDetection && Sim == False && ConfirmNb <
ConfirmNb){
2.          State = OutOfTopic;
3.          ConfirmNb = 0;
}
4.      if (state == NewTopicDetection && Sim = True && ConfirmNb <
Tconfirm){
5.          State = NewTopicDetection;
6.          ConfirmNb++;
}

```

```

7.          if(State == NewTopicDetection && Sim == True && ConfirmNb
≥Tconfirm){
8.              State = InTopic;
9.              ConfirmNb = 0;
}
10.         if(State == InTopic && Sim == True){
11.             State = InTopic;
}
12.         if(State == InTopic && Sim == False){
13.             State = EndTopicDetection;
14.             ConfirmNb = 0;
}
15.         if(State == EndTopicDetection && Sim == False && ConfirmNb
< Tconfirm){
16.             State = EndTopicDetection;
17.             ConfirmNb++;
}
18.         if(State == EndTopicDetection && Sim == True && ConfirmNb <
Tconfirm){

```

```

19.          State = InTopic;
20.          ConfirmNb = 0;
21.          if(State == EndTopicDe-
22.          tection && Sim == False && ConfirmNb
23.          ≥ Tconfirm){
24.              State = OutOfTop-
25.              ic;
26.              ConfirmNb = 0;
27.          }
28.          if(State == OutOfTopic &&
29.          Sim == False){
30.              State = OutOfTop-
31.              ic;
32.          }
33.          if(State == OutOfTopic &&
34.          Sim == True){
35.              State = NewTopic-
36.              Detection;
37.              ConfirmNb = 0;
38.          }
39.          }
40.      End;

```

As indicated in Hearst (1995), the field of information retrieval has traditionally focused on textbases consisting of titles and abstracts. Hearst (1995) developed an algorithm called TextTiling that partitions expository texts into multi-paragraph segments that reflect their subtopic structure. The name TextTiling was used because the segments are adjacent and non-overlapping.

MAIN FOCUS OF THE CHAPTER

The main focus of this chapter is to summarize research contributions by other investigators in areas related to data linkage discovery. As this is a research area that was initiated in the 1990's it is necessary to discuss some of these and later milestone contributions that lead to the current state of research in linkage discovery.

The below Table 1 provides a new tabular summary of some of the work that was both discussed in Segall & Lu (2014) and is also contained in this chapter but reorganized by data linkage

Table 1. Categorization of data linkage techniques

Data Linkage Technique	Data Linkage Technique	Representative Articles	Other Properties or Characteristics
Algorithms	① Latent Semantic Analysis (LSA) ② TOPICOLL ③ TextTiling ④ Maximum Entropy (ME) ⑤ Latent Dirichlet Analysis (LDA) ⑥ Field Association ⑦ Latent Semantic Indexing (LSI)	① Foltz (1996) ② (Ferret(2002) ③ Hearst (1997, 1995, 1993) ④ Chua et al. (2004) ⑤ Liu et al (2009) ⑥ Sharif et al. (2007) ⑦ Zekikovcitz and Hirsh (2002)	① text-based research ② using collocations ③ segmentation by multi-paragraph subtopic passages ④ for large broadcast news video archives ⑤ interactive topic based ⑥ dictionary applications ⑦ nearest neighbor text classification
Text decomposition/segmentation	① Passage retrieval ② Text segmentation ③ Field association terms	① Salton et al (1993) ② Ponte & Croft (1997) ③ Atlam et al. (2003)	① full text information systems ② by topic ③ documents similarity measurements
Semantic similarity estimation	① ontology-based ② emergent semantics ③ word sense disambiguation ④ corpus-based	① Sanchez and Batet (2011) ② Markines et al. (2009) ③ Patwardhan et al (2003) ④ Mihalcea and Corley (2006)	① biomedical domain ② social tagging ③ semantic relatedness measures ④ knowledge-based measures
Frameworks	① Digital libraries ② Silk link discovery framework ③ semantic link discovery	① Fox and Sornil (1999) ② Volz et al. (2009) ③ Hassanzadeh et al. (2009)	① information retrieval ② for web of data ③ relational data

techniques. Table 1 categorizes the data linkage techniques into techniques of algorithms, text decomposition/segmentation, semantic similarity estimation, and frameworks.

Algorithms

According to Foltz (1996), Latent Semantic Analysis (LSA) is a statistical model of word usage that permits comparisons of semantic similarity of textual information. Foltz (1996) summarized how three experiments that illustrates how Latent Semantic Analysis (LSA) can be used in text-based research. Perez et al. (2005) performed a study for automatic assessment of students' free-text answers using a combination of Latent Semantic Analysis with an algorithm previously used by others for evaluating machine translation systems.

Chua et al. (2004) discussed techniques, experience and trends in story boundary detection in large broadcast news video archives that entails segmentation of news videos. The techniques employed by Chua et al. (2004) include sophisticated machine learning models based on Maximum Entropy (ME) approaches, and concluded that it is advantageous to employ rigorous machine learning techniques with full multi-modality features to achieve good segmentation performance.

Liu et al. (2009) built an interactive, visual text analysis tool that aids users in analyzing a large collection of text. Liu et al. (2009) used a Latent Dirichlet Analysis (LDA) model that effectively conveys complex text summarization results. The work of Liu et al. (2009) also describes a set of rich interaction tools that allows users to work with a created visual text summary to further interpret the summarization results in context and examine the text collection from multiple contributions.

Reynar (1994) presented an outline for a new automatic method of finding topic boundaries and performed experiments on a series of concatenated documents using an optimization algorithm. The experiments performed by Reynar (1994) were on the same data set that consisted of 150 concatenations of articles containing a total of 660 articles

averaging 24.5 sentences in length. The difference between the two experiments in Reynar (1994) was that in the first experiment, boundaries were placed only at the ends of the sentences while in the second experiment; they were only placed at paragraph boundaries. Reynar (1994) showed that high recall rates can be obtained in the first experiment and high precision can be obtained in the second.

Sharif et al. (2007) discussed how using field associations (FA) that are a discriminating set of discriminating terms that can specify document fields can yield improvement of building field association term dictionary. Sharif et al. (2007) used field association with a dictionary composed of 38,372 articles and yielded about 24% more relevant more relevant FA terms that are appended to the earlier FA term dictionary and about 32% irrelevant FA terms are deleted.

Hearst and Plaunt (1993) discussed the merits of subtopic structuring for full-length document access by describing a new way of specifying queries on full-length documents. Hearst and Plaunt (1993) described an experiment in which making use of the recognition of how local structure achieves better results on a typical information retrieval task than does a standard information retrieval measure. Hearst (1997) implemented an algorithm called TextTiling that segmented text into multi-paragraph subtopic passages.

Wang & Si (2008) proposed two probabilistic models to formally model the evidence of a set of top ranked passages in a document, and performed an extensive set of experiments to show the effectiveness of each model and better results in comparison with a state-of-the-art document retrieval algorithm and a language model approach for passage-based retrieval.

Hersh et al. (1995) indicated that all of the methods currently used to evaluate information retrieval systems have limitations in their ability to measure how well users are able to acquire information. Hersch et al. (1995) utilized a new approach for measures of information retrieval evaluation by accessing information obtained based on the user's

ability to answer questions from a short-answer test. Experiments were performed by Hersch et al. (1995) with senior medical students using a ten-question test and then have them search one of two information retrieval systems on the five questions for which they were least certain of their answer. Hearst (1995) presented a visualization paradigm called TileBars that demonstrates the usefulness of explicit term distribution information in Boolean-type queries.

Zelikovcitz & Hirsh (2002) integrated background knowledge into nearest-neighbor text classification using Latent Semantic Indexing accessing document similarities in training and test documents.

Text Decomposition/Segmentation

Salton et al. (1996) performed automatic text decomposition using text segments and text themes. Salton et al. (1996) presented two main decomposition strategies that include a chronological decomposition into “text segments” and semantic decomposition into “text themes”. Choi et al. (2009) discussed lower and upper bounds for linkage discovery using graphical methods.

Ponte and Croft (1997) investigated text segmentation by topic and presented experimental results for an effective method that makes use of a query expansion technique to find common features for the topic segments. According to Ponte and Croft (1997), the applications of the method discussed include topic tracking of broadcast speech data and topic identification in full-text databases.

Atlam et al. (2003) outlined a new text manipulation system named FA-Sim that is useful for retrieving information in large heterogeneous texts and for recognizing content similarity in text excerpts. FA-Sim measures texts similarity by using specific field association (FA) terms instead of comparing all text information. Experiments performed by Atlam et al. (2003) showed precision and recall improved by 39% and 37% respectively over these two traditional methods.

Salton et al. (1993) discussed new approaches for implementing selection passage retrieval systems, and identifying text passages responsive to particular user needs, and used an automated encyclopedia search system to evaluate the usefulness of the proposed methods.

Semantic Similarity Estimation

Pivovarov and Elhadad (2012) presented a hybrid knowledge-based and data-driven approach to identifying semantically similar concepts in biomedical texts. Pivovarov & Elhadad (2012) proposed a comprehensive method that computes a similarity score for a concept pair by combining data-driven and ontology-driven knowledge. Pivovarov & Elhadad (2012) demonstrated their method on a corpus of clinical notes of patients with chronic kidney disease, and their method was able to prune out concepts that are similarly related from those that are semantically similar with accuracy of 92%.

Sanchez and Batet (2011) discussed semantic similarity estimation in the biomedical domain using an ontology-based information-theoretic perspective. According to Sanchez & Batet (2011) semantic similarity estimation is an important component of analyzing natural language resources like clinical records. Sanchez & Batet (2011) found that an information-theoretic redefinition of well-known semantic measures and similarity coefficients, and an intrinsic estimation of information content (IC) result with accuracy.

Pedersen et al. (2007) discussed how six-existing domain-independent measures originally based on WordNet, an English lexical database of concepts and relations can be adopted for semantic similarity and relatedness in the biomedical domain. Pedersen et al. (2007) concluded that there is a role both for more flexible measures of relatedness based on information derived from the body of documents, as well as for measures that rely on existing ontological structures.

Corley and Mihalcea (2005) introduced a method that combines word-to-word similarity

metrics into a text-to-text metric, and showed that this method outperforms the traditional text similarity metrics based on lexical matching. Sukkarieh et al. (2003) used auto-marking as a means of using computational linguistics to score short free text responses.

Markines et al. (2009) evaluated similarity measures for emergent semantics of social tagging. Experiments with resource and tag similarity performed by Markines et al. (2009) have pointed to folksonomy-based mutual information measures as the best at extracting semantic associations from social annotation data. Patwardhan et al. (2003) used measures of semantic relatedness for word sense disambiguation and conducting experiments using a lexical sample data and found that a semantic distance measure and floss overlap resulted in the highest accuracy. Mihalcea & Corley (2006) presented a method for measuring the semantic similarity of texts, using corpus-based and knowledge-based measures of similarity, and showed that the semantic similarity method outperformed methods based on simple lexical matching, resulting in up to 13% error rate reduction with respect to the traditional vector-based similarity metric.

Resnik (1999) presented a measure of semantic similarity in an “is a” taxonomy based on the notion of shared information content. Experimental evaluation by Resnik (1999) against a benchmark set of human similarity judgments demonstrates that the measure performs better than the traditional edge counting approach for application of ambiguity in natural language.

Frameworks

Hassanzadeh et al. (2009) presented a framework for online discovery of semantic links from relational data that is based on declarative specification of linkage requirements by the user that allows matching data items in many real-world scenarios. Hassanzadeh et al. (2009) claim that their framework for semantic link discovery over relational data lets data publishers to easily find

and publish high quality links to other data sources, and therefore could significantly enhance the value of the data in the next generation of web.

Kobayashi and Takeda (2001) discussed the development of new techniques targeted to resolve some of the problems associated with Web-based information retrieval, and speculate on future trends. Fox & Sornil (1999) reviewed and organized into a simple framework some of the developmental efforts related to digital libraries that have been in the information retrieval area, and highlighted needs of the future. Volz et al. (2009) created a link discovery framework called Silk for the Web of Data that accesses data sources over a protocol without the need to replicate datasets locally.

Zamir and Etzioni (1999) introduced Grouper a dynamic clustering interface to Web search engine results. Grouper developed and tested by Zamir & Etzioni (1999) dynamically groups the search results into clusters labeled by phrases extracted from document snippets. Milne et al. (2007) created a new search engine called Koru that offers effective domain independent knowledge-based information retrieval that is powered by Wikipedia, and conducted a detailed user study and found that Koru and its underlying knowledge base offers significant advantages over traditional keyword search. Marchionini (2006) explained that research tools for exploratory search success involve the creation of new interfaces that move the process beyond predictable fact retrieval.

Keim (2002) proposed and exemplified using examples of a classification of information visualization and visual data mining techniques that is based on the data type to be visualized, the visualization technique and the interaction of distortion technique.

FUTURE RESEARCH DIRECTIONS

In future, we will work on summarizing the additional references provided below in the Additional Readings section that were found upon the

writing of this chapter. Each of these Additional Readings will also need to be categorized with the possibility of additional categories.

CONCLUSION

The chapter shows that considerable work has been done by investigators on the topic of data linkage discovery for many applications using techniques that include algorithms, text decomposition/segmentation, semantic similarity estimation, and frameworks.

Linkage discovery has found many new methods for efficient and effective connecting of documents using extensions of data and text mining and is a field that is continuing to be investigated by researchers around the world.

KEY TERMS AND DEFINITIONS

Glossary: An alphabetical list of terms in a particular domain of knowledge with the definitions for those terms (Wikipedia, 2016).

Information Retrieval: The activity of obtaining information resources relevant to an information need from a collection of information resources. Searches can be based on metadata or on full-text indexing.

Information-Theoretic: Based upon information theory such as subfields of information security and language processing.

Latent Semantic Analysis: Statistical model of word usage that permits comparisons of semantic similarity between pieces of textual information (Foltz, 1996).

Linkage Discovery: Applications include discovery of linkage between different sections in electron publications.

Ontology-Based: Borrowing a word from traditional philosophy

Record Linkage: About how to find matching records or duplicates among entities and sections within or across files.

Semantic Analysis: In linguistics is the process of relating syntactic structures, from the levels of phrases, clauses, sentences and paragraphs to the level of the writing as a whole, to their language-independent meanings (Wikipedia, 2016).

Exploratory Data Analysis on Breast Cancer Prognosis

INTRODUCTION

Breast cancer is the most common female cancer in the US, the second most common cause of cancer death in women (“American Cancer Society”, 2016), and the main cause of death in women ages 40 to 59 (Siegel et al., 2012).

In 2016, it is estimated that 249,260 new cases of breast cancer will be diagnosed and estimated 40,890 breast cancer deaths; and an invasive breast cancer will be diagnosed in about 246,660 women and 2,600 men. An additional 61,000 new cases of in situ breast cancer will be diagnosed in women (“American Cancer Society”, 2016). The lifetime probability of developing breast cancer is one in six overall (one in eight for invasive disease) (“American Cancer Society”, 2013; Siegel et al., 2012).

Worldwide, breast cancer is the most frequently diagnosed cancer among women in 140 of 184 countries, according to the World Cancer Research Fund International (“BCRF”, n.d.). Since 2008, breast cancer incidence has increased by more than 20 percent and mortality has increased by 14 percent (“BCRF”, n.d.). Nearly 1.7 million new breast cancer cases were diagnosed in the last report of 2012.

Medical prognosis is an evaluative component of medicine that encompasses the science of estimating the complication and recurrence of disease and predictive survival of patients (Ohno-Machado, 2001). Medical prognosis plays an increasing role in health care outcome. Reliable prognostic models that are based on survival analysis statistics and techniques have been applied to a variety of domains with varying degrees of success (i.e., APACHE IV (Zimmerman, 2006)).

Breast cancer prognosis is a vital element of providing effective treatment for patients. It has become increasingly important that clinicians are provided with accurate prognostic information on which to base therapeutic decision as the range of options for the treatment of patients with breast cancer widens. A large number of factors, including tumor grade, tumor size, and lymph node status including other aspects may influence or correlate with prognosis for breast cancer patients.

Breast cancer prediction survivability has mainly been studied through clinical approaches, based on pathological factors such as tumor grade, tumor size and number of the positive lymph nodes, estrogen (ER), progesterone (PR), and human epidermal growth factor receptor 2 (Her2) receptors,

DOI: 10.4018/978-1-5225-2255-3.ch156

etc. Most studies are carried out in an effort to find factors that clarify the large unexplained variation in prognosis of the breast cancer patients. There is still uncertainty about the importance of most prognostic factors. There are other non-clinical factors such as age, ethnicity, obesity, and marital status that may have prognostic impact but are not used routinely in clinical practice.

This chapter is a survey of the significance of the non-clinical prognostic factors (i.e., age, ethnicity) in finding the prognosis for breast cancer patients. The National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) Public-Use Data (years 1977-2013; 421,056 records) ("SEER," n.d.) and the Howard University Cancer Center Tumor Registry (1995-2013; 1599 records) data were analysed. NPI (Nottingham Prognostic Index (Galea, 1992)) is a prognostic tool that enables grouping of patients based on calculated prognosis (i.e., excellent, good, moderate, poor) and the impact of each non-clinical prognostic factor on these subgroups. In addition, survival analysis tools such as Cox proportional hazards and Kaplan-Meier survival curve ("Cox proportional-hazards regression", 2013) were used in analyzing the data.

Our data analysis suggested that age, ethnicity, and marital status have some influence on the survivability rate of breast cancer patients. Whether such influence is significant enough in relationship with the clinical factors such as tumor size and grade remains to be further studied.

BACKGROUND

Several studies have been carried out on the survivability prediction of breast cancer using Naïve Bayes and Classification Trees, Artificial Neural Networks and statistical techniques of regression (Delen et al., 2005; Gupta et al., 2011). Delen and colleagues (Delen et al., 2005) have used data mining algorithms Artificial Neural Networks, decision trees, and logistic regression to develop

the breast cancer prediction models. The results indicated that the decision tree (C5) is the best predictor with 93.6% accuracy on the sample, artificial neural networks came second with 91.2% accuracy and the logistic regression models came to be the worst of the three with 89.2% accuracy.

Investigators (Owring & Hosseinkhah, 2013; Owring, 2014) have used the association rules data mining technique and data mining tool XLMiner ("XLMiner", n.d.) to investigate the significance of the ethnic factor on the patient's prognosis. The results, the association rules, suggested that the ethnicity had some significance in the survivability rate of the patient.

Existing reports suggest that young breast cancer patients have poorer outcomes compared to their older counterparts, which are in part attributed to later stage disease, more aggressive tumors, and less favorable receptor status (Anders, 2009; Bharat, 2009; Saghie et al., 2006). It appears that ethnicity may further influence breast cancer prognosis (Biffi et al., 2001; Liu et al., 2013). The large SEER Program and National Cancer Data Base analyses indicated that African-American women have more advanced disease at presentation and a higher death rate compared with non-Hispanic Caucasians. Investigators (Biffi et al., 2001) studied the influence of ethnicity on the prognosis of young breast cancer patients (≤ 35 years). Their study shows that Latino patients suffer more aggressive disease and poorer prognosis than other young women.

Most existing studies reflect single institution experiences that may not be representative of the whole population. Additionally, existing reports did not attempt to compare patients based on age and ethnicity relative to patients' prognostic group (i.e., excellent or good). This motivated us to examine the prognosis for breast cancer patients with respect to age, ethnicity, and marital status with a new approach based on patients' prognostic groups (i.e., excellent, moderate, good, poor).

BREAST CANCER PROGNOSIS

The prognosis of a patient diagnosed with cancer is often viewed as the chance that the disease will be treated successfully and that the patient will recover. Accurate prediction of survival is vital for planning effective breast cancer treatment.

To determine how appropriate a medical intervention is for a patient, physicians are required to estimate benefits and risks of each treatment based on their predicted prognosis. Oncologist most often use several factors to determine prognosis. The most common items are age, ethnicity, tumor stage, tumor size, nodal involvement, tumor grading, lymphovascular involvement, hormone receptor status, HER-2 receptor status and tumor differentiation (Bradley, 2007; Soerjomataram et al., 2008). They also may use a 23-gene panel (oncotype DX) to determine risk assessment for some early stage cancers. An exact percentage determination in most cases is not necessary as adjuvant therapy is given for most breast cancers. Prognostic determinants are very valuable in determining the necessity for aggressive therapy in early-stage breast cancers.

Breast Cancer Prognostic Factors

Although scientists do not know the exact cause of most breast cancers, they do know some of the risk factors that increase the likelihood of a woman developing breast cancer.

A prognostic factor may be defined as a measurable variable that correlates with the natural history of the disease. The prognostic factors used in the prediction of survival of breast cancer patient can be separated into two categories: chronological (based on the amount of time present, i.e., stage of cancer), or biological (based on the potential behavior of the tumor, i.e., histological grade) (Bradley, 2007; Soerjomataram et al., 2008).

Lymph node status, tumor size, histological grade are among the prognostic factors in use today (Bradley, 2007; Soerjomataram et al., 2008). Lymph node status is a time-dependent factor and

is directly related to survival. One of the most significant prognostic factors in breast cancer is the presence or absence of axillary lymph node involvement, which is usually assessed at the time of surgery using sentinel lymph node biopsy or axillary dissection (Bradley, 2007).

Survival is inversely related to the size of the tumor. The probability of long term survival is better with smaller tumor than with larger tumor (Soerjomataram et al., 2008). Tumor size has long been recognized as an independent prognostic factor and as a predictor of axillary node status, with larger tumors being associated with a poor prognosis and an increased likelihood of nodal metastasis.

Histological grade is being identified as being highly correlated with long term survival. Patients with a grade 1 tumor have a much better chance of surviving than patients with grade 3 tumor ("Breast Cancer," 2012). Delen (Delen et al, 2005) conducted sensitivity analysis on artificial neural networks model in order to gain insight into the relative contribution of the independent variables to predict survivability. The sensitivity results indicated that the prognosis factor "Grade" is by far the most important predictor, which is consistent with the previous research, followed by "Stage of Cancer", "Radiation", and "Number of Primaries". Why these prognostic factors are more important predictors than the other is a question that can only be answered by medical professional and further clinical and analytical studies.

Other factors include the patient's age, estrogen-receptor and progesterone-receptor levels in the tumor tissue, biological and genetic properties of the cancer cells (these properties, which are sometimes called biomarkers, can be determined by specific lab and imaging tests).

Breast Cancer Prognostic Tools

There have been efforts in building breast cancer risk assessment and prognostic tools. For example, National Cancer Institute (NCI) Breast Cancer Risk Assessment Tool ("National Cancer

Institute,” n.d.) uses a woman’s risk factors (i.e., age, menstruating at early age, older age at first birth or never having given birth, family history of breast cancer, etc.) to estimate her risk for breast cancer during the next 5 years and up to age 90. Multiparametric tools have been developed for breast cancer prognosis. These tools are briefly overviewed next.

Adjuvant! Online

Adjuvant! Online (“Adjuvant Online,” n.d.) provides the assessment of probability of survival and benefit from specific therapies (i.e., adjuvant) in patients with early breast cancer. The model takes into account age, menopausal status, comorbidities, ER status, tumor grade, tumor size, and number of involved axillary nodes.

PREDICT

PREDICT (“PREDICT,” n.d.), an online prognostication and treatment benefit tool designed to help clinicians and patients make informed decisions about treatment following breast cancer surgery. The survival estimates, presented both with and without adjuvant therapy (hormone therapy, chemotherapy), are provided for 5 and 10 years following surgery. The model uses the factors including patient age, tumor size, tumor grade, number of positive nodes, ER status, HER2 status, Ki67 status and mode of detection. Survival estimates, with and without adjuvant therapy, are presented in visual and text formats.

Nottingham Prognostic Index (NPI)

The Nottingham Prognostic Index (NPI) (Galea et al., 1992) is another prognostic tool used, widely in Europe, to determine prognosis following surgery for breast cancer. Its value is calculated using three pathological criteria: the size of the tumor; the number of involved lymph nodes; and the grade of the tumor.

The index is calculated using the formula: $NPI = [0.2 \times S] + N + G$, Where:

S is the size of the tumor in centimeters,
N is the number of lymph nodes involved: 0 =1, 1-3 = 2, >3 = 3,
G is the grade of tumor: Grade I =1, Grade II =2, Grade III =3

The interpretation is as follows:

Score 5-Year Survival Prognosis

≥2.0 to ≤ 2.4 93% Excellent Prognosis

> 2.4 to ≤ 3.4 85% Good Prognosis

> 3.4 to ≤ 5.4 70% Moderate Prognosis

> 5.4 50% Poor Prognosis

SIGNIFICANCE OF NON-CLINICAL PROGNOSTIC FACTORS ON PROGNOSIS

There have been some attempts to show that there are non-clinical factors including ethnicity, genetic, diabetics and obesity that may have prognostic impact on prognosis (Lan, 2014; Owrang, 2014). The results were found to have varying effects on breast cancer survival rates in different studies.

In the following, we describe the application of prognostic tool and statistical analysis in understanding the significance of the breast cancer prognostic factors. The two approaches can complement each other in providing a better estimate of the influence that a factor might have on the overall patient’s prognosis.

Significance of the Breast Cancer Prognostic Factors Based on Prognostic Tools

We have performed several analyses using NPI tool in order to show the significance of the non-clinical prognostic factors within different prognostic groups (i.e., excellent prognosis). The Adjuvant! Online and PREDICT have not been considered for the analysis as they are primarily used to calculate an individual patient’s prognosis.

Table 1. Variables considered in the analysis

Categorical Variable Name	Distinct Values
Behavior Code	4
Ethnicity	19
Marital Status at Diagnosis	6
Extension of Tumor	23
Radiation	9
Lymph Node Involvement	10
Grade	5
Diagnostic Confirmation	8
Stage of Cancer	5
Cause of Death	2
Primary Site	10
Continuous Variables	Range
Tumor Size (cm)	0-10
RX Summ -Surgery Primary Site	0-99
Number of Primaries	1-8
Number of Positive Nodes	0-50
Age at Diagnosis	17 – 102
ER status	2
PR status	2
HER2	2
Survival Time Recode Total Months	0 – 83

SEER's breast cancer dataset for the years 1977-2013 (421,056 records) has been analysed. Table 1 shows the attributes that are considered in the analysis.

Breast Cancer Prognosis Based on Ethnicity

Table 2 shows the calculated prognosis using NPI tool for different ethnic groups. In Table 2, the results suggest that there are differences in the survivability rates among ethnic groups. For example, in comparison of white and black patients, the calculated value for excellent prognosis is 19.31% and 11.8% respectively. To see if this disparity in the prognosis among ethnic groups is statistically significant, we have performed hypothesis testing (two sample proportion with summary) using StatCrunch statistical package ("StatCrunch," n.d.). For all categories of the prognosis (i.e., excellent prognosis), the hypothesis testing for the ethnic groups resulted in a P-Value <0.0001 in every case. The P-value indicates that we should reject the hypothesis that there are no differences within ethnic groups and that the differences between groups are statistically significant. Japanese patients have better survival rates than the other groups.

Table 2. Calculated prognosis using NPI prognostic tool for ethnicity

Ethnicity	Prognosis				
	Excellent	Good	Moderate	Poor	Total
Japanese	861	1161	1379	423	3824
%	22.52	30.36	36.06	11.06	
White	58044	80600	117634	44310	300588
%	19.31	26.81	39.13	14.74	
Black	4263	6882	16595	8387	36127
%	11.80	19.05	45.94	23.22	
Chinese	882	1323	2063	724	4992
%	17.67	26.50	41.33	14.50	
Others	2135	3558	6057	2427	14177
%	15.06	25.10	42.72	17.12	

Breast Cancer Prognosis Based on Marital Status

Similar analysis has been performed to study the significance of the marital status on breast cancer prognosis using the NPI tool (Table 3). The results suggest that married patients have better prognosis than single (never married, widowed, divorced) patients.

Breast Cancer Prognosis Based on Age

We have analysed Howard University breast cancer dataset using NPI prognostic tool. We considered patients of age (45 or less) as young and (45 plus) as old.

Table 4 shows the NPI prognostic categories (excellent, good, moderate, poor) for the younger and older black breast cancer patients.

Table 4 shows comparison between black younger and older patients such that values for “poor prognosis” is 37.74% and 25.97% respectively. The younger patients have less chance of

survival than the older patients. We have tested the differences using a two proportion sampling with summary hypothesis testing. A P-value of <0.0029 has been obtained, signifying that the difference is statistically significant. On other prognostic categories (i.e., excellent, good, and moderate), there is a difference between the younger and older patients; however, the difference is not statistically significant ($P\text{-value} \geq 0.05$). The findings from Table 4 can be summarized as prognosis tends to be poor in younger black women than in older black women and the difference is statistically significant, only on the “poor prognosis” category. However, such differences in other prognostic categories (i.e., moderate) are not statistically significant. This result, off course, can be hindered by small sample sizes.

To further investigate the notion that age (younger ≤ 45 and older > 45) has correlation with worse prognosis, we have used NPI tool on SEER breast cancer data set (1998-2013) with more than 400,000 records. Table 5 shows the results for the different prognostic categories for younger and older black and white patients. Simi-

Table 3. Calculated prognosis using NPI prognostic tool for marital status

Marital Status	Prognosis				
	Excellent	Good	Moderate	Poor	Total
Married	39007	54622	84040	30980	208649
%	18.70	26.20	40.30	14.80	
Single	25076	36196	56100	23828	141200
%	17.70	25.60	39.70	16.90	
P-Value	<0.0001	0.0003	0.0012	<0.0001	

Table 4. NPI prognosis categories based on ethnicity and age for Howard University Breast Cancer Dataset

Black/ Age	Prognosis								
	Excellent	%	Good	%	Moderate	%	Poor	%	Total
≤ 45	4	2.52	19	11.95	76	47.80	60	37.74	159
> 45	34	4.91	127	18.3	352	50.79	180	25.97	693
P-Value	0.19		0.05		0.50		0.0029		

lar to Howard University breast cancer dataset, data analysis shows that black younger patients (30.40%) compared to older patients with (21.49%) have “poor prognosis”. That is, the younger black patients have lower survival chance than the older black patients. We have tested the difference using a two proportion sampling with summary hypothesis testing. A P-value of <0.0001 confirms that the difference is statistically significant. With respect to “moderate prognosis”, the younger black patients have higher percentage than the older ones. The difference is statistically significant. That is, the younger are doing better than the older patients. Considering the “excellent” and “good” prognoses, the older black patients have higher percentages than the younger patients. In both cases, a P-Value of <0.0001 confirms that the differences are statistically significant. Therefore, the younger patients are faring worse than the older patients in these prognostic categories.

We should point out that in Table 4 (prognostic categories based on Howard University Data Set), the differences between the young and old black patients in the prognostic categories of “excellent”, “good”, and “moderate” were not statistically significant.

Considering young white patients in Table 5, similar to young black patients, they also have higher percentage of “poor Prognosis” (22.05%) than older white patients (13.55%). The difference is of course statistically significant. Regarding the other prognostic categories of excellent, good, and moderate, the differences between the young and

old white patients were also statistically significant (P-Value <0.0001). Overall, older white patients are doing better than the younger patients in every prognostic categories.

Breast Cancer Prognosis Based on Age and Ethnicity

Considering Table 5, on the “poor prognosis” category, the younger black patients have higher percentage (30.40%) than the younger white patients (22.65%). The difference between the two ethnic groups is statistically significant. This result suggests that the younger black patients have higher rate of poor prognosis than the white counterpart. Likewise, for the “moderate prognosis”, the difference was statistically significant. Similar results have also been observed for older black and white patients for the “poor prognosis” and “moderate prognosis” categories.

On the “excellent prognosis” and “good prognosis”, young black patients have lower percentage compared to young white patients. The difference between the two ethnic groups is statistically significant. This shows that younger black patients are doing poorer than younger white patients. Similar results have been observed regarding the older black and white patients.

Overall, young patients had worse prognosis when compared with the older group for the “poor prognosis” category, in both Howard University and SEER datasets.

Table 5. NPI prognosis categories based on ethnicity and age for NIH SEER Breast Cancer Data set

Ethnicity /Age	Prognosis								
	Excellent	%	Good	%	Moderate	%	Poor	%	Total
Black									
≤45	472	6.74	901	12.87	3499	49.99	2128	30.40	7000
>45	3791	13.02	5981	20.53	13096	44.96	6259	21.49	29127
P-Value	<0.0001		<0.0001		<0.0001		<0.0001		
White									
≤45	4460	11.34	7488	19.04	18471	46.97	8906	22.65	39325
>45	53584	20.51	73112	27.98	99163	37.96	35404	13.55	261263
P-Value	<0.0001		<0.0001		<0.0001		<0.0001		

Significance of the Breast Cancer Prognostic Factors Based on Statistical Analyses

Several statistical methods can be identified to rank prognostic factors based on their influence on the outcome of a disease. These schemes include Multivariate Data Analysis (Peat, 2005), Sensitivity Analysis (Peat, 2005), and Survival Analysis (Peat, 2005; “Cox proportional-hazards regression”, 2013). Cox proportional hazards model (“Cox proportional-hazards regression”, 2013) has been used extensively on a modelling approach to the analysis of survival data. The purpose of the model is to simultaneously explore the effects of several variables on survival.

We have used the Cox model to estimate the hazard ratio associated with each breast cancer prognostic factor. The hazard function is the probability that an individual will experience an event (for example, death) within a small time interval, given that the individual has survived up to the beginning of the interval. It can therefore be interpreted as the risk of dying at time t . Interpreting the Cox model involves examining the coefficients for each explanatory variable. A positive regression coefficient (the B value) for an explanatory variable means that the hazard is higher and thus the prognosis is worse. Conversely, a negative regression coefficient implies a decreased hazard and increased survival times. Exp (B) is the ratio of hazard rates that are one unit apart on the predictor. As an example, if the predictor age has a coefficient of 0.03, then the hazard rate increases by 0.03 (3%) with each unit increase in age.

Table 6 shows the result of running the Cox regression hazard ratio for the SEER breast cancer using the IBM SPSS Statistical software for PC. It shows that except for the ethnic factor, other factors have higher hazard and thus the prognosis is worse. A negative regression coefficient for ethnicity implies a decreased hazard and increased survival time.

Table 6. Cox Regression Hazard Ratio for the SEER breast cancer dataset 1977-2013

	B	Sig.	Exp(B)
Tumor_Grade	.185	.000	1.203
Lymph_Nodes_positive	.016	.000	1.016
New_Ethnicity	-.053	.000	.948
New_Marital_Status	.099	.000	1.104
New_Age_Group	.239	.000	1.270
New_ER_status	.369	.000	1.447
New_PR_status	.477	.000	1.612
New_Tumor_Size	.429	.000	1.536
New_HER2	.022	.038	1.001

While Cox model compares covariates on overall hazard ratio, Kaplan-Meier survival curve (“Cox proportional-hazards regression”, 2013) compares the groups within a factor. It can be used to assess the statistical significance of any observed differences in a single covariate. Figure 1 shows the Kaplan-Meier survival curve for the ethnicity factor. It is the test of equality of surviving distribution for the different levels of the ethnicity factor. The graph shows that Japanese patients, first line from the top, have the best survival rate, followed by Chinese, Others, White, and Black Patients (2nd, 3rd, 4th, and 5th lines from the top of the graph, respectively).

Similar result has been obtained for the Marital Status factor based on Kaplan-Meier survival curve which shows that married patients have higher survival rate than single (windowed, divorced, never married) patients.

FUTURE RESEARCH DIRECTIONS

Current medical literature suggests that factors such as eating habit, work/occupational environment, genetics and family history, obesity could influence the survivability rate. More experiments should be conducted based on these factors to determine their impact on the prognosis. In addition, we must study the process in which existing

Figure 1. Kaplan-Meier survival curve for ethnicity prognostic factor
(1=White, 2=Black, 3=Japanese, 4=Chinese, 5=Others)

breast cancer prognostic tools (i.e., NPI) can be extended in order to accommodate the non-clinical prognostic factors in finding the survivability rate of breast cancer patients more accurately. Factors can be ranked based on their significance on the overall survivability (using sensitivity analysis, feature/factor selection, principle component analysis etc.) and weighted according to their ranking. Finally, such extended prognostic tool/system need to be evaluated for its usefulness in a clinical practice environment.

CONCLUSION

Accurate prediction of survival is an essential part of the decision making process following surgery for early breast cancer which allows clinicians to determine which patients will benefit from a treatment (i.e., Adjuvant therapy).

Breast cancer prognosis is generally understood through clinical approaches based on prognostic factors such as tumor grade, tumor size, lymph node status, ER, PR, Her2 receptors among others.

The aim of this chapter was to better understand the influence that non-clinical factors such as age, ethnicity, and marital status might have on breast cancer prognosis. Data analysis have been performed using the NPI prognostic tool, COX proportional hazard ratio and Kaplan-Meier survival curve to see if non-clinical factors have any impact on the overall survivability rate of the breast cancer patients.

Overall, data analysis indicates that breast cancer patients have different survivability rate considering their age, ethnicity, and marital status and such disparities in the final prognosis are statistically significant in most cases.

KEY TERMS AND DEFINITIONS

Breast Cancer: A malignant (cancerous) growth that begins in the tissues of the breast in an uncontrolled way.

Data Analysis: The process of systematically applying statistical and/or logical techniques to describe and evaluate data.

Prognosis: The prediction of the survivability from a disease.

Prognostic Factor: A measurable variable that is used in the prediction of survival of breast cancer.

Prognostic Tool: A software tool that uses risk factors (i.e., age, ethnicity, genetic) to estimate breast cancer survivability rate.

Survival Analysis: A field in medical prognosis that deals with the application of various methods to estimate the survival of a particular patient suffering from a disease.

Survivability Rate: The probability of surviving and recovering from a disease.

D

In-Memory Analytics

Jorge Manjarrez Sánchez

Instituto Tecnológico Superior de Jerez, Mexico

INTRODUCTION

Processing speed and data set volume are a challenge for traditional analytics systems. Consider when do you want to make a recommendation for an online customer: right there while she is still browsing your catalogue or next time (if) she returns back? When do you want to detect a credit card is fraudulent: before a transaction is committed or after a client complain some days later? Score or decide when a credit card transaction is fraudulent or an incoming email is spam, is relatively easy from a computationally point of view provided the appropriate algorithms are implemented correctly. But in real-life systems where hundreds of thousands of such transactions arrive simultaneously and the correct decision must be taken instantaneously or in near real-time, speed is crucial. Even though only for the second example question an incorrect false negative, i.e., the no detection of a fraud, can have severe negative consequences, these examples highlight two main challenges in data analytics: the need to process ever larger data volumes and the need of obtaining fast or real time results. These are the concerns of In-memory analytics.

In what follows, we provide a definition and some concepts necessary to understand the problem and solution approach of in-memory analytics. Then we present a review of some important technological proposals to deal with two main challenges in data analytics: speed and scalability. The presentation is made from a data management perspective, independent of their nature (structured or unstructured), because an efficient data management strategy provides the infrastructure to handle and enable fast access to voluminous data sets for their analytical processing.

DOI: 10.4018/978-1-5225-2255-3.ch157

BACKGROUND

Analytics is the processing of data for facts and information discovery. Embedded within data there are facts about some events, perhaps several and a variety of them. These facts are knowledge helpful for taking decisions, recommendations systems, fraud detection, sentiment analysis in social networks and customer identification and many other applications. In a broad sense analytics can provide an answer for questions such as what happened? Why did it happen? What will happen? What should I do? And they correspond to the task of descriptive, diagnostic, predictive and prescriptive analytics respectively. The answer to these questions are obtained by the application of techniques from statistics, machine learning and computer science in the processing of data.

Analytics is the processing of data for making sense of all of it. Data sets are very large and to process them one has to cope with two orthogonal concerns: accuracy and speed of results. Accuracy needs to process as much data as possible, not just random samples. Not using complete datasets leads to loss of information (Wang, Callan, & Zheng, 2015) and obtained responses are approximations with certain level of error. Accuracy of the statistical model and henceforth that of predictions are proportional to samples size and quality. The bigger the better, but even that we can have today larger data sets, their processing takes considerable time. It consumes more processing time and disk input/output (IO) operations because data must be swapped back and forth from hard drives to RAM and CPU caches. But due to speed differences in data access and transfer between these devices, there is a processing bottleneck. One approach to avoid IO processing bottlenecks is to use as

much as possible RAM memory, hence the name In-Memory Analytics, where data is loaded and kept into RAM for their fast consumption by the processing algorithms.

FAST ANALYTICS

In this section we address the speed challenge. When the speed of results is a factor to consider for efficient analytics, and taking into consideration that it must be used as much data as possible for the abovementioned reasons, then one must reduce or eliminate processing bottlenecks. They can be the IO latency and CPU usage. CPU is good at computing mathematical operations and multicore CPU's enhance their performance. IO depends on the type of disk and RAM. Solid state disks are faster than hard disk drives, but random access memory is faster. A typical hard drive has a latency of 5 ms while RAM has only 100 ns, it is 50000 times faster. But also the faster the more expensive. There is one more rapid type of memory: cache memory, which is a small and expensive memory within the CPU die. Main memory or In-memory refers to the processing of data performed in RAM.

The data management infrastructure provides the processing capabilities according to the workload type. The typical workloads in a database, can be Online Analytical Processing (OLAP) or Online Transaction Processing (OLTP). The difference between both are their usage patterns, size of result sets and processing speed. Traditionally OLTP deals with faster small transactions and OLAP seeks for answer precision on very large data sets, but nowadays speed is an important factor to provide for both of them, hence the use of in-memory analytics, the usage of RAM fast data access and to enhance analytics performance. But the issue is that real data sets are usually larger than the memory affordable and available in a system. Also note that not all available memory can be used for data storage, enough space must be allocated to handle temporary objects and

intermediate results of computations. To address this concern, one approach is to use compression. For instance, by using compression and column-based storage it is possible to reduce storage space because only required attributes are retrieved from disk. Additionally, compression leverages CPU ability to handle numbers instead of text which combined with columnar storage allows an application to keep large quantities of data in memory. A drawback is that this approach is read optimized, insert or update operations are not easy. Some other approaches to make efficient use of memory while computing intermediate results are discussed in (Duan, Li, Tang, Xiao, & Li, 2013) within the context of Spark, an open source in-memory analytics platform. Their proposal makes automatic management of the memory space used by intermediate results susceptible of being used in further computations instead of letting the full responsibility to the programmer.

The idea of in-memory databases is not new (Lehman & Carey, 1986), it has been studied since more than two decades ago, but nowadays it is possible for real enterprise applications to process larger amounts of data because of RAM price drops. In addition to high prices, there was a technical limitation of the operating systems for the addressing of larger memory beyond some GB. Today these limitations have gone and prices started to decrease and now it is common for a single server to have 1 TB of RAM and a cluster of computers to sum up several Terabytes. The scalability issue to cope with big data sets is the topic of the next section.

In-memory analytics appliances from major vendors integrate an optimized computer with an in-memory database. The main database vendors have developed their in-memory proposal: Microsoft Hekaton (Diaconu et al., 2013) is an engine integrated within SQL Server, the memory optimized part of the database is marked as memory optimization. Code of stored procedures can also be compiled to enhance CPU usage. Oracle TimesTen (Lahiri & Folkman, 2013) is a separate product that can also be used as a fast data cache

for the mainstream Oracle database. SAP HANA (Plattner, 2014b) is one of the first proposals for columnar in-memory databases. Recent HANA improvements can handle successfully OLAP and OLTP workloads. Evidently all these systems provide mechanisms such as logging to achieve durability, transaction processing with full ACID (Atomicity, Consistency, Isolation, Durability) support, and some ad hoc enhancements. For instance, TimesTen can be used almost directly on a grid of computers.

Even if some analytical algorithms are implemented within the database (in-database) to have direct access to data and hence minimize data movement, data must be loaded into RAM to allow computation. The advantage of in-database analytics is that programmed algorithms can make use of some database structures that accelerates data access in addition to security and fault tolerance. In (Ordonez, 2013) it is presented a survey of some statistical and machine learning techniques that have been implemented inside a DBMS. The same article elucidates some approaches to program new analytic algorithms as User Defined Functions when it is not possible to modify the source code. We argue that a combination of in-database with in-memory obtains a better solution, indeed the same article mentions that programmed procedures in C or a similar language allows to push some computations to main memory.

But in spite of drop in memory prices or elimination of technological barriers not all required data can fit into memory and nor all database management systems or their processes are optimized to work into memory. Hence the need for a scalable proposal based on the combination of in-memory processing with parallel and distribute settings.

SCALABLE ANALYTICS

Now we turn to the data volume challenge. Suppose you have enough memory in a single server to handle small to medium size data sets. It arises

the situation when memory or processing power of a single machine is not enough. The efficient design of a scalable analytics infrastructure have been studied in (Zhang & Ré, 2014) and (Otto & Weber, 2013) among others. Zhang proposes a framework called DIMMWITTED to test the behavior of Support Vector Machines, logistic regression, neural networks and Gibbs sampling. The aim is to analyze the access methods (row or column), model replication and data replication to find a balance in the design space of these considerations where the efficiency of the system is maximized. The results are a guide to the design and implementation of analytical systems with a 100 times speed up in comparison with their baseline. In summary, the experiments show that there is no difference between row or columnar data access. Model replication is better when it is performed per node (the alternative are per core and per machine). Finally, the data replication, considering it is immutable (which in practice it is not often the case unless it is read only or a snapshot of a database) they simply state that avoiding data skew is a sufficient condition for achieving good performance. This can easily be attained by simple round robin partitioning of data among available processing nodes of the cluster.

Among the parallel architectures, shared-nothing is a choice because of its capability to be built from commodity machines and easy scalability. Data is partitioned across several computing nodes which process subsets of the data and then coordinate to consolidate final results. In-memory computing is less constrained. It scales far beyond a single server by using distributed in-memory computing examples are Hazelcast, memcached and Apache Spark ("Apache Spark," n.d.), but even on them memory must be used efficiently (Duan et al., 2013).

Statistical or machine learning algorithms must not only take advantage of local or single server's main memory, but to transparently scale to be able to handle big databases by the efficient use available memory in cluster or cloud settings. Although there are proposals that already exploits

elastic computing power, such as RAMCloud (J. Ousterhout et al., 2015) which proposes an in-memory distributed DRAM cache with a key value data model with low latency and fail tolerance capabilities. Low latency is in the order of microseconds and is achieved by using high speed network interconnections and guarantees 1-2 seconds availability when recovery from a failure. As usual in distributed systems there is a master which coordinates replication and helps to recover from failures.

In (Xin et al., 2013) it is proposed an scalable analytical engine based on a distributed memory abstraction. The engine is based on the MapReduce (Dean & Ghemawat, 2008) framework but performs 100 times faster than Hadoop among other improvements. For our discussion, it is important to note the in-memory abstraction, that handles all the available physical memory in the cluster to process analytical queries and reconstruct data lost in failures. Why it is important? Because RAM is a volatile memory and it is its main weakness. More on this in a section below.

Several research efforts have been made into leveraging the MapReduce framework as a starting point to develop scalable machine learning algorithms. The advantage of MapReduce is that it frees the developer from tasks allocation, communication issues and failure recovery. Also scalability of a parallel task is handled by the framework which automatically uses the available processing nodes in the distributed machine. Even if this programming model has several disadvantages (Doulkeridis & Nørnvåg, 2013) it has been used successfully in several real analytical projects. Among its enhancements there are main-memory implementations. One concern is its expensive initialization phase, but if you have to process real big data sets in offline mode MapReduce or one of its implementations such as Hadoop is a good option. Because the savings in the processing of a big data set compensates its expensive starting. A

survey of the weakness and limitations along with the proposed solutions are discussed in (Doulkeridis & Nørnvåg, 2013)

Probably one of the most notable in-memory open source implementations of MapReduce for analytics is Spark (Zaharia et al., 2012) a follow up of the project Shark (Engle et al., 2012; Xin et al., 2013), which provides tens fold speedup over Hadoop. Main Memory MapReduce, M3R (Shinnar, Cunningham, Herta, & Saraswat, 2012) aims at providing a fast MapReduce by eliminating communication overhead of the JobTracker and the heartbeat and promoting reuse of already in-memory structures.

Several machine learning algorithms used for descriptive analytics using unsupervised learning techniques such as the famous k-means (Jain, 2010) has also been implemented in MapReduce. It is unsupervised because it does not use predefined labels, it simply starts and discovers clusters of data based on their similarity. Its uses are varied and innumerable. For instance, it can be applied to discover frauds or lawbreakers or something out of normal by running the clustering process over the data points. After finishing the clustering process, the remaining data points (those that do not belong to any cluster) are called outliers. If each data point in a cluster represents a typical or acceptable behavior, then the outliers are the misbehaved ones. K-means is a computationally expensive algorithm that exemplifies that many analytical algorithms perform several scans over the data set imposing a strong overload in the IO system and thus is a viable candidate for in-memory implementation. Also to efficiently handle large data sets a parallel framework like MapReduce is often used. In (Bahmani, Moseley, Vattani, Kumar, & Vassilvitskii, 2012) a parallel version of k-means that perform an efficient initialization algorithm is proposed. Initialization is the finding of the centroids for each cluster, their choice and their number determines the quality of the clusters obtained.

FUTURE RESEARCH DIRECTIONS

Main memory is faster but their volatile nature makes it more sensitive to failures and data can be lost. This can be alleviated by implementing some failure recovery protocols, such as one based on checkpoints that saves database state at some intervals and in the presence of failures allows for recovery to the most recent saved state. Some recent research also proposes strategies for non-volatile persistence (Narayanan & Hodson, 2012).

New technologies arise to improve performance of computer applications. CPU speeds and efficiency constantly improves as well as that of RAM. A new type of storage aware non-volatile memory is being developed, it has the persistency capabilities of hard drives but preserving the speed of volatile RAM. Some prototypes have been developed to test their efficiency proving promissory results (Bailey, Hornyack, Ceze, Gribble, & Levy, 2013; S. Chen & Jin, 2015). These prototypes are based on memristors and phase-change memory which needs some improvement because of their write operations' latency, although they are still faster than solid state disks. Another drawback is that they are inconsistent with today block-oriented file systems. A recent work (Kimura, 2015) obtains positive experiments for the scalability of an ad hoc in-memory database for 240 cores and newly-emerging non-volatile memory (NVRAM).

If you want to optimize memory usage at a finer level, then consider the case of efficient CPU cache utilization. Cache is very small but faster than RAM. It is from there where the processor takes data and instructions to execute. If they are not available the processor stalls, simply meaning it does nothing. So when a programmer wants to exploit all the processor power, she must avoid cache misses and maximize cache hits. In (Tözün, Gold, & Ailamaki, 2013) experiments show that most misses come from the storage manager, specifically the indexing method in the processing of OLTP workloads.

Another research topic is related with the engineering of the software. Leveraging in-

memory processing with well-crafted off-the-shelf algorithms so data scientists or data analysts can concentrate on the design of experiments and interpretation of results without worrying about engineering high-performance algorithms.

Some other concerns are presented in (Tan et al., 2015). We do not discuss them here, because they relate to a general approach to data management and are not specific to analytics. However, as a further lecture, it can provide some clues about the issues to be solved and related to parallelism, concurrency and communication. Finally, one aspect we have not considered is the freshness of data: in order to have valid analytical results they should not be computed on stale data. So algorithms for in-memory updates or synchronization with the current data produced or stored on disk must be implemented.

CONCLUSION

Most of the statistical and machine learning algorithms required to perform analytical processing are iterative and pass over the data multiple times (take for instance the k-means algorithm). Handling the data on disk imposes a processing bottleneck and reduces system efficiency. In-memory analytics is a powerful approach to deliver fast and reliable data insights. Drop in prices and technological advances of RAM makes it affordable to have systems with larger memories capable of storing larger data sets.

IO operations are still an issue even if some new results seems to contradict this believe (K. Ousterhout, Rasti, Ratnasamy, Shenker, & Chun, 2015), but the fact is that even in that paper, it is stated that CPU is a remarkable issue because of the data compression used to save memory space. Hence, in reality the IO bottleneck is not solved, instead it is shifted to another vital resource: the CPU. Thus in the design of high performance analytics systems, one must make a tradeoff between sacrificing CPU at the cost of having a little extra space in memory by using some data compression

method or engineering efficient in-memory aware algorithms or perhaps spent some extra bucks into have a larger available memory. Memory savings are also obtained when serialization is used: data set size reduce up to three or more times but again, the corresponding deserialization mechanism required to process data consumes CPU and we are just shifting costs from one side to another.

KEY TERMS AND DEFINITIONS

Data Analytics: The processing of data for information and facts discovery.

Descriptive Analytics: The gathering and processing of data to determine and understand

the state of things in an enterprise, gives an answer to what happened?

In-Memory Computing: Computer processing performed by loading all data in RAM in order to speed up data access.

Machine Learning: The science of developing techniques to give the computer inference and deduction capabilities to achieve diverse processing tasks autonomously.

Predictive Analytics: The analytics of data for forecasting outcomes, provides an answer to what will happen, based on estimates issued from probabilities and statistical analyses.

Prescriptive Analytics: After knowing the current state and the likelihood of the outcomes, prescriptive analytics concern is to provide guidance or advise on what an enterprise should do.

Scalability: It is the capability of a system to handle bigger workloads without compromising performance.

Innovative Formalism for Biological Data Analysis

Calin Ciufudean

Stefan cel Mare University, Romania

INTRODUCTION

Modern medical devices involves information technology (IT) based on electronic structures for data and signals sensing and gathering, data and signals transmission as well as data and signals processing in order to assist and help the medical staff to diagnose, cure and to monitors the evolution of patients. By focusing on biological signals processing we may notice that numerical processing of information delivered by sensors has a significant importance for a fair and optimum design and manufacture of modern medical devices. We consider for this approach fuzzy set as a formalism of analysis of biological signals processing and we propose to be accomplished this goal by developing fuzzy operators for filtering the noise of biological signals measurement. We exemplify this approach on neurological measurements performed with an Electro-Encephalograph (EEG).

We mention that automatic diagnosis based on fuzzy approach becomes more and more used in artificial intelligence framework of proposing new methods and tools for developing automatic medical diagnosis. Fuzzy techniques of analysis and diagnosis have a significant advantage compared to classical techniques, respectively the ability to deal with typical uncertainty and estimation that characterizes any physical system, including the human body.

This chapter is focused on reasoning with fuzzy logic for designing new type of filters capable to reject noises which overload the biological signals taken by invasive ad/or non-invasive medical tools. We will exemplify our approach on EEG measurements. This goal will be accomplished by using a

new structure and inference mechanism of fuzzy operators which will implement a new design of filters against impulsive and uniform distributed noise. This approach is inspired by the class 1-D (signals) and 2-D (images) of fuzzy filters proposed in (Zadeh, 1988; Russo & Ramponi, 1994; Russo, 1994). Building our approach we were guided by Professor Lofthi Zadeh's statement (Zadeh, 1988): "Fuzzy logic is a precise conceptual system of reasoning, deduction and computation in which the objects of discourse and analysis are, or are allowed to be, associated with imperfect information. Imperfect information is information which in one or more respects is imprecise, uncertain, incomplete, unreliable, vague or partially true". We assume that the reader is familiarized with fuzzy logic systems, or we address the reader to (Kumar, s.a., 2001; Adlassnig, 2007; Chin, 1991; Fathi-Torbaghan & Meyer, 1994; Nguyen & Kreinovich, 2001; Bounds, 1999). We notice that literature treat intensively the subject of applying fuzzy logic to biological data acquisition and processing for medical diagnosis (John & Innocent, 2005; Perner, 2002); therefore we try to add a piece in this puzzle hoping to speed up the process of having a clear picture. Automatic processing of sensory information is an actual research area, and fuzzy techniques are well framed in this content, and represents a useful and widely applicable technique with long run perspective. This chapter is focused on implementing rule-based fuzzy systems for processing, e.g. filtering, measured biologic data in order to determine the availability of the most important ones for the final diagnosis. We appreciate that our approach will framework the

computer systems for medical diagnosis. An example will emphasize our approach.

This chapter is organized as follows: section 2 briefly discuss the chapter's position on the topic of biological data processing and analysis, section 3 presents our fuzzy filter approach, section 4 deals with fuzzy inference mechanism for filtering electric signals, section 5 illustrates our approach by an example and section 6 concludes the present work and gives a few directions for future research in the area.

BACKGROUND

As modern world evolves, so does the technique, economy, the life style, and unfortunately, the diseases; therefore, nowadays mainly due to stress, pollution and rush life style we confront with a new medical problem: the diagnosis of multiple diseases and the diagnosis of mutant diseases. Therefore, nowadays mainly due to stress, low infrastructure facilities and rush life style we confront with a new problem: the diagnosis of multiple informational news and data releases of mutant informational transmission infrastructure. Failure diagnosis in complex information systems, such as medical ones, is a critical task due to respect the safe development of these systems and patient care. In an optimistic scenario, doctors are confronted with patients who suffer from one disease and the diagnosis tries to find the cause and the most adequate treatment (Cacioppo & Tassinari, 1990; Lyons, Budynek, & Akamatsu, 1999). This approach give birth to classic diagnosis, e.g. to ordered tables or lists well known in medicine as well as in medical informatics that make a correspondence between symptoms and disease (Ekman, Levenson, & Friesen, 1983; Ekman, Friesen, & Ellsworth, 1972; Posner, Russell, & Peterson, 2005). In our view this is only the starting point for developing a new way for applying computational modeling techniques in medical diagnosis procedure. This is explained by the fact that while in the above mentioned rule-based

systems deterministic models are considered (e.g. there are facts determined by certain factors), our approach deals with dependent probabilities of medical symptoms, signs and tests, and therefore we model the diagnosis procedure with artificial intelligence formalisms, such as fuzzy sets.

We assume that diagnosis of patients implies some risks and also some possible human errors or lack of an adequate logistics such as materials, equipment, medical devices, etc. (Pearl, 1988; Perner, 2006, 2008).

Basically, the doctors' expertise based on clinical symptoms, physical examination and laboratory results are the foundation for a correct diagnosis and treatment procedure for the patients. In order to optimize this complex process and to help performing correct computational modeling diagnosis our paper focuses on fuzzy built-in diagnosis procedure (Picard, Vyzas, & Healy, 2001; Groshan, 2012). An advantage of our model is that the use of large fuzzy models is not required. Another advantage is that it allows performing sensitivity analysis of an entire flexible system, as well as of its components. The novelty of this approach is that it incorporates the availability of the human factor, as fuzzy approach usually does, and in order to deal with this issue we built a fuzzy filter capable to reject both human and machine errors in medical data transmission and processing, e.g. capable to reject errors of patient diagnosis.

We consider for this approach fuzzy set as a formalism of analysis of biological signals processing and we propose to be accomplished this goal by developing fuzzy operators for filtering the noise of biological signals measurement. These fillers are capable to reject impulsive noise as well as the uniform noise in a very large proportion. The design of such filters is simple, starting by choosing the number of neighbors used for the correction, and obtaining an, easy to implement inference approach (Gadoras & Mihailev, 2009; Sharifalundian, 2009).

We exemplify this approach on neurological measurements performed with an Electro-Encephalograph (EEG) device.

PROPOSED FUZZY FILTER

In this section we present the design of fuzzy, systems devoted to the filtering of noisy measurement data. For this purpose, we shall focus on an interesting, and unfortunately not so much implemented, developments of a family of rule-based fuzzy operators, called FIRE (Fuzzy Inference Ruled by Else-Action) operators (Russo & Ramponi, 1994). The basic principle upon which these operators are based has been originally proposed in (Russo, 1994); now, FIRE operators represent a rapidly growing family of operators for 1-D and 2-D signal processing, as demonstrated by the number of applications in which these operators have become competitive with the classical techniques.

In the next section it will be presented the design of a new class of FIRE operators, e.g. Basic Support of Fuzzy Filters (BSFF) operators as we entitled them, whose filtering behavior can be adapted in order to address uniformly impulsive and distributed noise. Such a filter is based on the following features:

- An optimal choice of fuzzy sets;
- A new interference mechanism.

Let $d(n)$ be a digitized input signal in the range $(0, D-1]$. Let $d_0 = d(n)$ be the sample to be processed at time n , and let $M = \{d_i\}$ be the set of K neighbouring samples which belong to a window centred on d_0 , respectively $M = \{d_1, d_2, \dots, d_K\} = \{d(n-K/2), \dots, d(n-1), d(n+1), \dots, d(n+K/2)\}$, without d_0 .

The input signals of the filter are defined as the amplitude differences as follows:

$$a_{in} = d_i - d_0 \quad (1)$$

Where $i \in (1, K)$, and $a_{in} \in [-M+1, M-1]$

The output parameter a_{adj} represents the adjusting term added to sample d_0 for obtaining the new sample d_{01} :

$$d_{01} = d_0 + a_{adj} \quad (2)$$

Fuzzy sets for the input and output variables are defined in the domain of the amplitude differences. For this purpose, we use triangular-shaped fuzzy sets defined by two parameters (see Figure 1); where R and b represent the center and the half-width of the fuzzy set, respectively. We adopt, in particular, three fuzzy sets labelled *positive strict* (PS), *zero* (Z), and *negative strict* (NS), (John & Innocent, 2005).

The typical rule base of the fuzzy filter includes two symmetrical sub-rule bases and one ELSE-rule, thus identifying three different consequent actions.

Basically, the operation of the fuzzy rule base can be described by the following statements:

IF the value of a sample is higher than those of its neighbors. THEN decrease its amplitude;

IF the value of a sample is lower than those of its neighbors. THEN increase its amplitude;

ELSE do not change it.

More formally, the rule base of the fuzzy filter is expressed as follows:

Figure 1. Triangular fuzzy set used for building BSFF

IF (a_{in1}, A_{11}) AND... AND (a_{inK}, A_{1K}) THEN (a_{adj}, PS)

IF (a_{in1}, A_{21}) AND... AND (a_{inK}, A_{2K}) THEN (a_{adj}, PS)

IF (a_{in1}, A_{n1}) AND... AND (a_{inK}, A_{nK}) THEN (a_{adj}, PS) (3)

IF (a_{in1}, A_{11}) AND... AND (a_{inK}, A_{1K}) THEN (a_{adj}, NS)

IF (a_{in1}, A_{21}) AND... AND (a_{inK}, A_{2K}) THEN (a_{adj}, NS)

IF (a_{in1}, A_{n1}) AND... AND (a_{inK}, A_{nK}) THEN (a_{adj}, NS)

ELSE (a_{adj}, Z) .

Where A_{ij} is the fuzzy set (PS or NS) associated to the input variable number j in the rule number i . Rules having PS as the consequent set constitute the *first* sub-rule base; rules having NS as the consequent set constitute the *second* sub-rule base.

Fuzzy rules are designed in order to suppress noise while preserving the signal (Ndiaye, 2009); therefore the group of antecedent clauses of each rule takes care of a particular class of neighboring samples. Since the sub-rule bases in relations (3) are symmetrical, we can completely identify the structure of a particular operator by specifying only the group of fuzzy sets A_{ij} ($i = 1, \dots, n$, and $j = 1, \dots, K$). For this purpose, let A be the $(n \times K)$ matrix where elements a_{ij} are defined as follows: $a_{ij} = 0$ if $A_{ij} = PS$, and $a_{ij} = 1$ if $A_{ij} = NS$.

Using this matrix, we shall compactly define the rule base of any BSFF operator.

FUZZY INFERENCE MECHANISM

In order to describe the particular inference mechanism of the filter, we denote by C_1 and C_2

the degrees of activation of the first and the second sub-rule base, respectively. These degrees are evaluated by means of the following relationships (Gullapalli, 1990; Clouse, 1996; Guerrin, 1991), see Figure 1:

$$C_{1,2} = \max\{\min[m_{A_{ij}}(a_{inj})], \text{ with } i = 1, \dots, n, \text{ and } j = 1, \dots, K\} \quad (4)$$

Let C_0 denote the degree of activation of the ELSE-rule, where this degree is evaluated by using the following relation:

$$C_0 = 1 - (C_1 + C_2) \quad (5)$$

It should be observed that the ELSE-rule is reinforced by a weak activation of the other sub-rule bases. By adopting correlation-product inference (Guerrin, 1995), the output a_{adj} can be evaluated by using the following relationship, see Figure 1, and Figure 2:

$$a_{adj} = (R_{PS} \cdot b_{PS} \cdot C_1 + R_Z \cdot b_Z \cdot C_0 + R_{NS} \cdot b_{NS} \cdot C_2) / (b_{PS} \cdot C_1 + b_Z \cdot C_0 + b_{NS} \cdot C_2) \quad (6)$$

From relation (1) and considering fuzzy triangular-shaped represented in Figure 1, and the fuzzy sets defined in Figure 2, we have:

$$R_{PS} = -R_{NS} = M-1; R_Z = 0 \quad (7)$$

$$b_{PS} = b_{NS} = b_Z = 2(M-1) \quad (8)$$

Figure 2. Fuzzy sets of BSFF

Thus, relation (6) becomes

$$a_{adj} = (M-1) \cdot (C_1 - C_2) \quad (9)$$

We mention that the fuzzy set parameters given by relations (7) and (8) represents the *optimal* parameters as this parameters allow a noise pulse to be rejected once it has been detected.

ILLUSTRATIVE EXAMPLE

Let V be the set of two neighboring samples defined by $V = \{d_{01}, d_{02} = \{d(n-1), d(n+1)\}$, where $K = 2$. The input variables a_{in1} and a_{in2} are consequently defined by relation (1). We can define a new fuzzy capable to suppress impulsive noise by using six THEN-rules.

$$\begin{aligned} &\text{IF } (a_{in1}, PS) \text{ AND } (a_{in2}, PS) \text{ THEN } (a_{adj}, PS) \\ &\text{IF } (a_{in1}, PS) \text{ AND } (a_{in2}, NS) \text{ THEN } (a_{adj}, PS) \\ &\text{IF } (a_{in1}, NS) \text{ AND } (a_{in2}, PS) \text{ THEN } (a_{adj}, PS) \end{aligned} \quad (10)$$

$$\text{IF } (a_{in1}, NS) \text{ AND } (a_{in2}, NS) \text{ THEN } (a_{adj}, NS)$$

$$\text{IF } (a_{in1}, NS) \text{ AND } (a_{in2}, PS) \text{ THEN } (a_{adj}, NS)$$

$$\text{IF } (a_{in1}, PS) \text{ AND } (a_{in2}, NS) \text{ THEN } (a_{adj}, NS)$$

$$\text{ELSE } (a_{adj}, Z).$$

The corresponding matrix A_{adj} is represented below:

$$A_{adj} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix} \quad (11)$$

For exemplifying our approach we addressed the curtesy of the Medical Center Areni Suceava, Romania, which allow us to assist some EEG signals recording. By medical ethic reasons we erased from the following figures the patient name; Figure 3 displays the EEG measured from patient X, (Gadoras & Mihailkov, 2009; Sharifalundian, 2009; Perner, 2008).

Figure 3. EEG signals measured from patient X

Figure 4. The active area of patient's brain measured by EEG signals

The chart showing the active area of EEG signals measured during the medical investigation time, and processed with a classic tool used by neurologist doctors, e.g. Neuro-Soft is shown in Figure 4. Light colors show the most active zone of the patient's brain.

In order to show the performance of the proposed operator, we have adopted a test waveform of EEG signals measured in an inadequate relational data transmission between the EEG and the computer used for register the EEG's waves and to process them according to our approach.

Basically, we used a non-insulated cable for data transmission which eventually results in intolerably fluctuating transmission path impedances which corresponds to adding impulsive noise (Perner, 2006, 2008).

We processed the biological EEG signals first with a classic tool used by neurologists, e.g. Neuro-Soft, and then we exported them in ASCII format in a Matlab environment in order to apply our approach (Figure 5).

In Figure 6 we display one of the 21st signals measured by EEG complex shown, i.e. signal Fp1A1 in Figure 3, which has been first processed on a time window in Matlab environment; here the signal is severely distorted as we mentioned before. Applying relations (10) and (11), e.g. by applying our fuzzy operator for the above mentioned signal we obtain the signal shown in Figure 7; as it can be seen, the noise has been severely diminished by almost 60%.

We repeat the procedure for all 21 EEG signals displayed in Figure 3 in order to filter the EEG signals, and finally we obtain the right power spectrum of each component of the filtered signals in Figure 8, i.e. the power spectrum of patient X's EEG.

CONCLUSION

Automatic processing of sensory information is an actual research area, and fuzzy techniques

are well framed in this content, and represents a useful and widely applicable technique with long run perspective.

This chapter is focused on implementing rule-based fuzzy systems for processing, e.g. filtering measured biologic data. Our work resumes the researches of (Russo, 1994) focused on the filtering of noisy signals, and we propose an approach for filtering electrical signals encountered in biological measurement here entitled Basic Support of Fuzzy Filter (BSFF), as a new class of FIRE (Fuzzy Inference Ruled by Else-Action) operators. These fillers are capable to reject impulsive noise as well as the uniform noise in a very large proportion. The design of such filters is simple, starting by choosing the number of neighbors used for the correction, and obtaining an, easy to implement inference approach (Gadoras & Mihailkov, 2009; Sharifalundian, 2009).

One drawback of our method is that it necessitates more experiments in order to find out more appropriate certainty factors for a large range of diseases. However, as far as we experienced our approach under physicians' supervision at the Medical Center Areni Suceava, it proves to be a realistic way to improve the medical interaction physician (or nurse) – patient, as it allows us to modify in real time certainty factors.

FUTURE RESEARCH DIRECTIONS

An interesting extension, to be considered in future work, would consist of introducing a feedback mechanism that promotes the dynamic updating of the certainty factors considered as fuzzy weights (associated with different medical rules) according to the current patient status.

KEY TERMS AND DEFINITIONS

Automatic Processes: A category of cognitive processing.

Availability: The degree to which a system, subsystem is in a specified operable and committable state at the start of a mission, when the mission is called for at an unknown, *i.e.* a random, time.

Data Analysis: A process of inspecting, adapting, and modeling data with the goal of discovering useful information and decision making.

Diagnosis: Identification of the nature and cause of anything.

Electroencephalography: (EEG): A monitoring medical procedure to record electrical activity of the brain.

Fuzzy Logic: A mathematic analysis formalism which deal with concepts that cannot be expressed as the “true” or “false” but rather as “partially true” similar to human operators thinking.

Inference Mechanism: A tool from artificial intelligence analysis formalisms which addresses the search and control techniques.

Neurologist: A medical specialist in the nervous system.

Learning From Imbalanced Data

D**Lincy Mathews***M. S. Ramaiah Institute of Technology, India***Seetha Hari***Vellore Institute of Technology, India*

INTRODUCTION

Pattern Identification on various domains have become one of the most researched fields. Accuracy of all traditional and standard classifiers is highly proportional to the completeness or quality of the training data. Completeness is bound by various parameters such as noise, highly representative samples of the real world population, availability of training data, dimensionality etc.

Another very pressing and domineering issue identified in real world data sets is that the data is well-dominated by typical occurring examples but with only a few rare or unusual occurrences. This distribution among classes make the real world data inherently imbalanced in many domains like medicine, finance, marketing, web, fault detection, anomaly detection etc.

This chapter aims to highlight the existence of imbalance in all real world data and the need to focus on the inherent characteristics present in imbalanced data that can degrade the performance of classifiers. It provides an overview of the existing effective methods and solutions implemented towards the significant problems of imbalanced data for improvement in the performance of standard classifiers. Efficient metrics for evaluating the performance of imbalanced learning models followed by future directions for research is been highlighted.

BACKGROUND

The field of data mining has identified learning from data that suffer from imbalance distribution

as one of the top problems of today (Yang & Wu, 2006). However, a widely accepted issue is that the traditional learning algorithms assume a balanced distribution among the classes. It does not address nor recognize the presence of imbalance in the data. Data imbalance is evident when the number of instances representing the class of concern is much lesser than other classes.

To cite an example, the 1999 KDD Cup data set (UCI machine repository) is considered. The information collected by a simulated LAN environment consists of normal traffic with a relatively small number of intrusion attempts. The original data set consists of 23 classes, of which one of the classes belonged to normal traffic. When the data set was grouped down to a total of 2 classes, 'normal' and 'attack', the KDD data had 972,781 minority 'attack' class examples and 3,925,650 majority 'normal' class examples, which is approximately 80.14% majority examples. The training data thus will have only very few samples from the 'attack' class, due to which the classifier will be biased to the normal cases. This under representation of the interested class is evident in many applications such as intrusion detection, pollution detection, fault monitoring, biomedical, bioinformatics and remote sensing.

The under-represented class and well-represented class are known as the positive class (denoted by +1) and negative class (denoted by -1) respectively. As the class of interest indicates a positive case and is rarer by nature, it represents the minority data. The research community addresses the other well-defined classes as majority

class. The ratio between the instances of majority versus minority is termed as imbalance ratio.

The skew distribution present in the training data, leads to the bias by most classifiers. Studies have however shown that the base classifiers perform well when presented with balanced data than with imbalanced data (Weiss & Provost, 2001). This justifies the need for learning models that can address the challenges posed by imbalanced data.

CHARACTERISTICS OF IMBALANCED DATA

The imbalance ratio between the majority and minority instances need not necessarily affect the performance of classifiers if the degree of imbalance is moderate (Chen & Wasikowski, 2008). The inherent characteristics within minority data however; can cause degrade in performance by the learning models. Two basic categorization of minority instances exist; Safe and unsafe minority instances. Safe minority instances are instances where the misclassification is minimal by the base learners. These instances exist much away from the borderline of majority instances. Unsafe minority instances are so called because the misclassifications occur highly with these kinds of minority instances.

The causes of unsafe instances in imbalanced data sets are contributed by four significant occurrences. They are the presence of small disjuncts, lack of density in the sample space, noisy data and data shift. Addressing these issues alone can sometimes bring a positive effect on the accuracy of the classifier without having to address the imbalance factor (Japkowicz N, 2003).

Small disjuncts exist when there is a small cluster of similar instances amidst cluster of majority or minority instances. However, in case of imbalanced datasets, the presence of sub concepts (disjuncts) in the majority class will be rare as they are represented well. The occurrence of small disjuncts is frequent in minority class. The presence of small sub concepts can undermine the

performance of the classifier. As the data space; is very limited, this can lead to generalization and over fitting by the learning models. Weiss (2003) had identified the presence of disjuncts in imbalanced datasets as noise or sub concepts. Synthetic (artificial) samples were generated for these small disjuncts to overcome the lack of representation.

Lack of density is the existence of small sample size. Lack of samples coupled with high dimensional data becomes an even more difficult issue in imbalanced data. This creates rules that are too specific and can lead to over fitting. In domains such as face recognition, gene expression analysis etc; feature reduction method such as the Principal Component Analysis were used to address the high dimensional problem with respect to sample size (Yang et al., 2008). One sided or two sided feature selection technique addressed this problem (Alibeigi, 2012).

Presence of noise or outliers creates a negative impact on the performance of the classifier. As outliers occur much away from minority instances, it is most likely treated as noise. However, it might represent the rarest of cases that should be recognized and classified. There are cases of overlapping instances; presence of similar instances in majority and minority instances. These samples seemingly are the hardest to classify. The authors (Garcia et al., 2008) proposed two different frameworks for the k-Nearest Neighbor (k-NN) classifier. They focused on the ratio between the imbalance in the overlapping region versus the overall imbalance ratio. Khoshgoftaar et al. (2011) analyzed the relation between noise and imbalanced data. Bagging and boosting techniques were applied after implementing noise reduction techniques.

The data shift problem is realized when the training data distributions differs from the distribution of the test data (Alaiz & Japkowicz, 2008). The data shift phenomenon is mostly due to sample selection process. Stratified cross validation is used to measure performance thus avoiding sudden drift in performance. The other cause could be due to a very high degree of imbalance. Presence of data shift can highly affect the singular classification

error due to the low number of instances it has (Moreno et al., 2010). Preprocessing techniques can address the data shift problem.

TECHNIQUES FOR LEARNING FROM IMBALANCED DATA

The solutions proposed are categorized into data driven techniques, cost sensitive techniques and algorithmic solutions.

Data Driven Techniques

The aim is to change the distribution of data. Some mechanisms are applied to alter the imbalanced distribution of the data to a balanced distribution. One of the effective and efficient methods under data driven techniques is the sampling method.

Random sampling involves sampling of data to alter the skew distribution of existing data. Random under sampling involves random elimination of majority instances. This technique however, might eliminate informative samples that can affect the classifier performance while reducing the size of majority class. Random over sampling, appends instances to the minority class by sampling from the minority data. This naturally leads to over fitting and cause computational burden on the algorithm.

To overcome the deficiency of random under sampling, Informed under sampling selects majority samples that are redundant or acted as noise in classifying minority instances. Yen et al. (2009) proposed a cluster based approach; by clustering the majority instances from where the representative samples were then selected from each cluster as instances. Yua et al. (2013) selected significant and informative majority instances as per the selection frequency. This process however proved to be time consuming than the simple sampling procedure.

Synthetic Sampling, an over sampling technique was one of the powerful technique that proved to be a success in many applications. This

technique initially was adopted to address the high dimensionality problem. Synthetic Minority Oversampling Technique (SMOTE) (Chawla, 2002) generated instances by creating samples between nearest neighbor minority samples using the distance measure. The synthetic sample is defined as a point on the line joining a minority instance and its nearest neighbor; i.e., where, r is a random number between 0 and 1, x_i is the selected minority instance and, x_{nn} is nearest neighbor to. Synthetic instances generated closer to the majority class could be noise instances for the majority samples and can lead to overlapping.

Seetha et al. (2012) developed a novel multiple kernel learning approach to generate a synthetic training set larger than the original training set. This addressed the underperformance of Support Vector Machine (SVM) when the training sample had a very high dimension data. Viswanath et al. (2006) proposed a novel synthetic pattern generation by performing the join of sub patterns. The curse of dimensionality that affected the performance of Nearest Neighbor classifier was reduced significantly. Synthetic patterns to address the imbalance problem using the techniques mentioned in paper are currently being studied by the authors of the chapter.

Adaptive sampling techniques were proposed to overcome the overlapping limitation. Synthetic samples are generated based on the category of minority instances. Bartosz et al. (2014), proposed weighted one class classifier and adjusted weights depending on the type of minority instances - safe, borderline, rare and outlier. Random oversampling and SMOTE were used to improve the distribution of the data for increase in performance by decision tree, neural networks and SVM (Kerdprasop and Kerdprasop, 2012).

Cluster Based Clustering (CBC) approach deals with within-class imbalance problem. Yong (2012) proposed an approach where synthetic samples are produced using the genetic approach with the k- means classifier. Yen & Lee (2009) formed clusters of training data (majority class). The representative samples from the clusters were

selected as majority samples. Results showed that the cluster based under sampling improved prediction accuracy. Vasu & Ravi (2011) combined k means clustering on the negative class with k-reverse nearest Neighbor (kRNN) to detect outliers. The superiority of the method were effectively proved by classifiers such as SVM, Genetic programming and decision tree.

Another technique used is the Sampling with boosting method. Thanathamath et al. (2013) combined boundary data generation with boosting procedures for efficient classification by the Adaboost Classifier. Using the Hausdorff distance, the class boundary data were identified and eliminated. The training data was augmented by bootstrapping and synthesizing the new boundary area. Myoung et al. (2015) used geometric mean based boosting algorithm (GMBoost) to resolve data imbalance problem. The proposed method showed better performance than adaboost and cost sensitive boosting.

Features or dimensionality of the data plays an important role for the efficient and unbiased performance of classifiers. One Sided selection identifies features relevant to the class of interest. Two-sided selection identifies relevant features pertaining to both the classes. Feature selection metrics such the Chi square, Information Gain etc handles attributes if binary and nominal. Other metrics used for continuous data are Pearson Correlation Coefficient, Feature Assessment by sliding threshold etc. The probability density estimation of features for small disjuncts but with high dimensional data sets were used as the features selection criteria in Density Based Feature Selection (DBFS) (Alibeigi et al., 2012). DBFS in combination with correlation between features were adopted. K-S tree based on Kolmogorov-Smirnov proposed by Gong et al. (2012) selected relevant features and removed redundant variables. Oversampling and under sampling the data, is then applied to balance the distribution of data.

Cost- Sensitive Based Learning

One of the efficient approaches attempted by the researchers to reduce the bias of traditional learners is the sampling technique based on balance ratio. In Cost Sensitive approach, however, the costs of misclassified instances are considered. When there is a misclassification, the cost of misclassifying a minority instance as majority instance is usually greater than the cost of misclassifying a majority instance. Studies have shown that cost sensitive learning methods are superior to sampling technique in certain domains (Liu & Zhou, 2006) such as fraud, medical diagnosis etc.

Three approaches are adopted under the umbrella of cost sensitive learning. The first method is to assign the cost to the data space based on hard to classify samples, density based, borderline samples etc. Thus, based on the cost, the best instances from the training samples are inducted for next iteration. The second technique is to modify the existing classifier algorithms by incorporating the cost sensitive functions or characteristics. The third class involves developing cost sensitive classifiers by combining ensemble algorithms with the traditional algorithms.

Y Sun et al. (2007) proposed three algorithms: AdaC1, AdaC2 and AdaC3. Each algorithm assigns a greater misclassification cost so that the classifier receives instances that are more relevant. Uyar et al (2006) used oversampling and under-sampling with adjusting of decision threshold. This technique achieved optimum true positive and true negative.

Cost adjustments are applied to the decision threshold, split criteria at each node and on different pruning schemes considering the decision tree classifier. Maloof (2003) applied the different decision threshold criteria with respect to the misclassification cost. ROC evaluation metric was used to arrive at the most dominant point on the Curve. The plot was done to analyze the per-

formance when the decision threshold is moved against the maximum cost earned by misclassification of positive class and negative class. In a standard decision tree, splitting criterion is based on minimum error at each node. Pruning was applied to decision trees to remove leaves with class probabilities less than a threshold. Japkowicz & Stephen (2002) showed pruning the tree modeled from imbalanced data demonstrated less performance when compared to pruning of such trees.

On implementing cost sensitive approaches in Support Vector Machine (SVM); Zhao et al. (2011) worked on weighted maximum margin criterion to optimize the kernel. The weighted margin between the minority and majority class is been maximized in this method. Hwang et al. (2011) embedded weight parameters in the SVM Lagrangian formulation to speed up training and performance of Lagrangian Support Vector machine (WLSVM). By transforming a multiclass imbalance problem into symmetrical two-class problem, Modular Neural Network (MNN) based on Divide and Conquer principle was proposed by Zhao (2009). It was less complex and showed better performance when compared to other Neural Network techniques.

Ensemble Based Methods

Ensemble methods are combinations of individually trained classifiers whose decisions are summed to arrive at the class of a new object. The performance is proportional to the accuracy and diversity of the base classifier. Efficiency is been improved by forming different learners based on different training data. The combination techniques usually are boosting and bagging.

SMOTEBoost (Chawla et al., 2003) algorithm produces synthetic instances on each boosting iteration. Thus, each ensemble gets a different training set that are well defined and separated among the classes. The distribution among classes is improved by adding new minority instances produced by SMOTE. Barandela et al. (2003) proposed ensemble classifier where the training

data is a balanced set of minority and majority instances. The number of majority instances under sampled without replacement is equivalent to the number of minority instances. Hence, every training set will contain the same minority instances but different majority instances.

Gue & Viktor (2004) proposed DataBoost-IM that generated synthetic samples based on the “hard to classify” samples. These instances formed the focus for the next classifier in the boosting procedure. Synthetic samples were used as against random sampling to avoid overfitting. Lia et al. (2012) developed a genetic algorithm that integrated over sampling and under sampling with an ensemble of SVM classifier. Synthetic instances were generated by using random distance to nearest neighbor by which the nearest neighbor support vector machines (NNSSVM) was generated. Boosting algorithm was used to assemble the NNSSVM. Zhang (2012) introduced a dynamic classifier ensemble method (DCEID). This model outperformed other ensemble strategies such as the weighted random forests and is based on the adapting ensemble which selected sample from the Dynamic Classifier selection and the dynamic ensemble selection.

Table 1 highlights the pros and cons of the three proposed methods for learning from imbalanced data.

EVALUATION METRICS

The commonly and traditionally used measure is the Classification accuracy (CA). For observing the bias of imbalanced data, the evaluation metrics for three different data under different learners are shown in Table 2. The numbers of positive instances versus negative instances are indicated against the domain.

As we see, the classification accuracy shows an above average performance against all classifiers for the all data given. This measure however, fails to identify the misclassification rate in their respective class. Gue & Viktor (2004) discusses

Table 1. Advantages and disadvantages of learning techniques

Method	Advantages	Limitations (Disadvantages)
Sampling Techniques	• Implementation is easy. • Data is affected but not the Classifier model	• Oversampling - o Increase in memory space - o Cause over fitting - o Time Consuming - o Quality of synthetic and existing data should be similar - o Computational Burden • Under Sampling - o Removal of informative and significant samples
Cost Sensitive Method	Minimize the bias of the classifier towards majority samples by reducing the cost of misclassification	• Error costs are often unknown and decided based on domain • Can lead to over fitting
Ensemble Methods	• More resistant to noise • Multiple classifiers provide better prediction than single classifier.	• Time consuming • Over fitting can occur

Table 2. Performance measures of various classifiers

Data-Domain with Ratio of Imbalance (+: -)	Classifier	Classification Accuracy	Specificity	Sensitivity	Precision
Liver Patient (167:416)	Nearest Neighbor	74.97	80.00	34.41	41.37
	Random Forest Tree	69.64	85.10	31.14	45.61
	Support vector machine	61.23	74.60	56.46	41.80
	Neural Networks	63.15	63.15	23.52	69.56
Satellite (626:5809)	Nearest Neighbor	91.62	97.06	67.99	71.76
	Random Forest Tree	94.33	98.66	54.15	81.29
	Support Vector machine	94.34	96.04	78.59	68.35
	Neural Networks	93.58	94.92	78.48	57.94
Blood Transfusion (178:570)	Nearest Neighbor	73.65	78.86	34.14	46.97
	Random Forest Tree	74.20	87.72	30.90	44.00
	Support vector machine	68.71	76.32	44.74	22.31
	Neural Networks	78.57	79.43	60.00	12.00

the ineffectiveness of for imbalanced data. The above examples show that base classifiers are sensitive to the distribution of data. In response to the ineffectiveness of the CA, other metrics, insensitive to the distribution of data used by the research communities are namely

, where TP-True Positives, FP-False Positive

, where FN-False Negative

Recall is known as sensitivity/TPRate for a binary-class data.. Further looking into the response values of sensitivity and specificity, as shown in Table 2, specificity values indicates a better prediction of majority samples. However, sensitivity indicates the degree of misclassification of positive instances. The number of patients been classified as affected by liver diseases is only 34% by the nearest neighbor classifier. The remaining were misclassified as non liver disease patients which is a huge error rate. Sensitivity of 60% in-

icates that 40% of patients were misclassified as patients who did not receive the blood transfusion. The table thus shows the necessity of specificity, sensitivity and precision. All the parameters are estimated through a contingency matrix.

, where β is the non-negative coefficient that adjusts the weight age between recall and precision. The value generally assigned is 1. F measure measures the effectiveness of retrieval. Precision is sensitive to data distribution but recall is not. Precision does not indicate the number of positive samples correctly classified.

Higher value of G-mean indicates maximization of accuracy of both classes and at the same time balancing accuracy of the two classes. However, these metrics does not address the performance of different classifiers over the same distribution.

For comparison and evaluating different classifiers, Receiver Operating Characteristics (ROC) curve is used. The ROC graph are plotted against TPrate and FPrate (Fawcett, 2006). This provides the visualization between tradeoffs and costs of classifiers with respect to the data distribution. For classifiers that produce discrete class outputs, the ROC is just a point on the graph. Any point on the left top part of the curve shows a good performance as TPrate should approach to 1 and FPrate to zero. For classifiers that output continuous numeric values, then a threshold produces a series of points.

ROC curves have its limitations. The ROC graph cannot indicate performance of classifiers if the number of false positives increases. There will not be significant change in the FPrate since it represents FP only minimally as it is a combination of FP and TN. Hence, the Precision Recall curve (Davis & Goadrich, 2006) is used. This curve is advantageous to measure the classifiers performance on highly skewed data as it indicates the change in False Positive. The values should approach to right top corner of the PR graph representing high value of precision and recall.

FUTURE CHALLENGES

Works highlighted in the chapter focused on learning from imbalanced data. However, several issues and challenges are yet to be investigated. One of the issues is to find to what degree the imbalance ratio should be reduced. Secondly, no unified framework exists. Thirdly, no specific approach has been singled out for imbalanced data in general. There is a need for standardized curve based evaluation metric to handle imbalance data. Algorithms that can handle incremental learning from imbalanced data streams need focus. Applying semi supervised learning to imbalanced data is also a pressing issue that ought to be addressed. Lastly, identifying unlabelled data using minimal training data also proves to be a challenge.

CONCLUSION

This chapter highlighted a very challenging and predominant issue in the field of machine learning: Learning from imbalanced data. The insights of the chapter aimed to cover the characteristics of imbalanced data that causes learner models to be biased. It discusses the state of the art solutions aimed at improving the classifier performance. It covers several efficient assessment techniques to analyze the performance over a range of situations. The opportunities and challenges available in the area of imbalanced data mining were highlighted for future research and development.

KEY TERMS AND DEFINITIONS

Bagging: It is the process of training multiple models on different samples (data splits) and averaging their predictions.

Bootstrapping: A statistical method generates artificial samples from the original training samples.

Classification: It is a process by which an unseen sample is assigned a class label by a model trained on data of known class labels.

Cost Matrix: A classification cost matrix is a matrix, where the element of value is the misclassification cost of guessing a case belongs to class X, when it actually belongs to class Y.

Overfitting: A modeling error that occurs when a function is too closely fit to a limited set of data point is known as Overfitting.

Sampling: It is a statistical analysis technique used to select, manipulate and analyze a representative set of data points in order to identify patterns in the larger data set.

Synthetic Data: It is defined as artificial generated data that is produced by some method.

Neighborhood Rough-Sets–Based Spatial Data Analytics

INTRODUCTION

With the huge amount of data generated every day, governments, corporates and scientists look at mining useful information from them. Considering the storage and organization costs of these data, the useful trade-off is to discover useful patterns in them. Transactional, telecommunication, spatial, satellite, remote sensing, medical informatics etc., are some of the domains dealing with *Big Data*. Discovering patterns and inferring predictions are vital to the well-being of man-kind at large. Analysis of spatial data usually includes construction of information system, dimensionality reduction, decision rule extraction based on a computational model and error analysis. This chapter focuses on the construction decision systems, proposes a hybrid method by substantiating the advantages and challenges involved with spatial data.

Spatial Data upholds an important perspective that it can be analysed only with respect to specific spatial reference (or a geographic area). Spatial data include spatial attributes like temperature, rainfall, humidity, slope, land cover etc., These features will be with respect to a spatial reference and encompass spatial auto correlation. Spatial auto correlation is the property of spatial data where the values of a feature will tend to be similar in a neighborhood and vary with increasing distance from the neighborhood. Figure 1 illustrates a sample region identified with latitudes and longitudes. A number of spatial features can be measured and some of them are shown in Table 1.

BACKGROUND

Mining spatial data is useful in fields like weather forecasting, natural calamity prediction, crime management, transmission and spread of infectious diseases and others. This calls for expertise in these areas and the nature of spatial data. For example, representing topology in spatial data modelling is inherent to dealing with uncertainties. And, Rough Sets have been used to deal with uncertainty in spatial data mining. Pawlak's (1982) Rough Set Theory (RST) has been used to model spatial regions with unclear boundaries. Beaubouef and Petry (1994) have demonstrated the use of rough sets have been used to query crisp data in relational databases. The Region Connection Calculus (RCC) proposed by Randell & Cohn (1992) and Egg-Yolk models by Cohn and Gotts (1996) have been blended with the ap-

Table 1. Sample Attribute Data of the region in Figure 1

Zones	Rainfall	Temperature	Slope
z1	21	18	1.6
z2	21	19	1.8
z3	22	19	2.1
z4	26	22	2.4
z5	16	28	1.4
z6	17	26	1.3
z7	19	27	1.7
z8	20	27	1.9

Figure 1. A sample geographic region

proximation concepts of RST to identify vague region boundaries. Rough sets have been used by Bai et. al (2010) to identify villages with birth defects, Ahlqvist (2005) for spatial classification and analysis, Leung et. al. (2007) for discovering classification rules in remote sensor data, Øhrn A (1999) for disease diagnosis and outcome prediction and Thangavel and Pethalakshmi (2006) for dimensionality reduction.

Spatial Data Analysis presents a myriad of challenges in modelling due to the uncertainty intrinsic to it. Spatial autocorrelation is yet another feature which presents the reference with core and periphery. And clearly RST can handle this with its approximation concepts.

Spatial Data: Challenges

RST uses equivalence relation to partition the universe which needs a discrete value space. Spatial Data involves continuous values and Jensen & Shen (2004) state that there may be loss of information upon discretization of continuous information. Lin (2000) proposed Neighborhood

Rough Sets and Dubois & Prade (2009), Fuzzy Rough Sets to solve this situation. Further, the granule of information supported in RST is based on partitions which yield single layer granulation structures. Neighborhood Rough Sets associate each element of universe with a family of Neighborhood granules which leads to multi-layered granulation.

Dimensionality reduction is also accomplished by rough sets based on indiscernibility. A subset of attributes that preserve the indiscernibility and henceforth induce the same partitioning of the universe are identified and called reducts. When applied on a spatial decision system, Bai & Ge (2009) say it is possible that some spatially relevant attributes may be removed while determining the reducts. It is comprehensive to treat spatial and non-spatial attributes separately. While most of the spatial attributes like temperature, rainfall, humidity, altitude etc., are continuous, using Neighborhood Rough Sets to identify knowledge granules will be accomplishing without the loss of information due to discretization.

This chapter will study the construction of a Spatial Decision System involving continuous and auto correlated spatial attributes for spatial data based on Neighborhood Rough Sets. It contains sections on Spatial Data Mining, Rough Sets on Spatial Data Mining; Rough Set based Decision Systems for Spatial Data Analytics, Neighborhood Granulation and Neighborhood Rough Sets. These sections discuss the current approaches, applications and prospects of the fields. Use of neighborhood based systems for spatial data is augmented with sections on coverings and spatial correlation. This is followed by conclusion and future directions of work.

DECISION SYSTEMS FOR SPATIAL DATA MINING

Spatial Data Mining probably dates back to the time ever since scientists started studying spaces and people. Environmentalists, epidemiologists, urban/highway planning authorities, demographers, market researchers, weather forecasters, retailers, telecommunication/automobile engineers, the defence and others have profound use in spatial data.

Scientists have been using Geographical Information Systems (GIS) and exclusive spatial databases to store, organize and retrieve spatial data. The rate at which the spatial data is being generated is colossal and this calls for studying patterns in them. Colocation pattern mining,

spatio-temporal mining, co-occurrence mining, identifying habitats – vegetation – dense areas, predicting bird nesting scenarios, crime analysis, spatial outlier significance, disease transmission modelling, identifying distribution of disease clusters, choosing a retail spot to outstand competition, analysing ocean data, land cover and associated prediction modelling are some of the mining problems extensively studied with respect to spatial data. This has led to informed decision making by the stakeholders, hence has led to the interest in exploring this area expecting only with more accuracy.

A sample decision system for spatial data is shown in Table 2. Komorowski et. al (1999) defined a *decision system* to consist of a finite set of objects constituting the universe U , a finite set of conditional attributes A , a set of decision attributes D and a value set V_a for A from the universe. The conditional attribute set in the decision system shown are $s1, s2, s3, s4$ and $s5$. The above sample has one decision attribute d . Constructing decision systems and applying soft computing techniques in spatial data mining has become inevitable. This is due to the accommodating nature of soft computing techniques like Rough Set Theory by Pawlak (1982), Fuzzy Sets by Zadeh (1965), their variants, enhancements and hybrid versions where they deal with inconsistent and uncertain data. These extensions of classical set theory with their unique properties have helped in resolving impacts due to data pitfalls. Besides, they also blend with other extensions like Neighborhood

Table 2. A sample decision system

object_id	s1	s2	s3	s4	s5	d
1	a	high	1.6	25-30	region1	yes
2	a	moderate	1.8	25-30	region2	yes
3	a	high	1.9	20-25	region1	no
4	b	massive	1.2	30-35	region3	yes
5	b	low	2.1	25-30	region1	no
6	c	massive	2.4	30-35	region2	no
7	c	low	1.5	20-25	region2	no

theories to overcome drawbacks and result in interesting findings.

The nature of data represented in decision systems should also be duly considered. Spatial data is entitled to unique features like high dimensionality, huge quantity, auto co-relation of attributes, involves a spatial reference and will include categorical or numerical attributes with discrete or continuous values. This chapter will include discussion on decision systems based on rough sets, fuzzy sets, rough fuzzy sets and Neighborhood systems.

ROUGH SETS IN SPATIAL DATA MINING

Pawlak proposed Rough Set theory (RST) in 1982 as an extension of classical set theory. RST expresses ambiguous sets using lower and upper approximation concepts. It created an approximate reasoning from the available data. This appealing nature of RST found its use in pattern recognition and mining problems. Researchers have used RST extensively for prediction modelling and dimensionality reduction. Øhrn (1999) enlists the use of RST in medicine, for predicting success of surgeries, myocardial infarctions, post-operative long & short term survival of patients, predicting diseases and length of treatment period. Bai et. al (2010) employ Rough Set Theory to identify distribution of neural tube defects in new born children. Dimensionality reduction using *reduct* of rough sets and identifying spatial factors involved in this defect were the highlights of the work. The work proved to be one of the eye openers to potential research in ecology, epidemiology and medicine.

Spatial data represents real world entities in spatial reference. Topological representations and relationships calls for handling without ambiguity. Association rule mining in SDM makes use of exclusive spatial topological relationships like *adjacent to*, *overlapping*, *intersection* etc., and such relationships between uncertain boundaries have to be addressed. Beaubouef and Petry

(2002) has demonstrated the use of fuzzy set approach for mining association rules with spatial factors involving topological uncertainty. They have suggested imbibing RST into data modelling will help in handling indeterminate nature of data. *RCC* and *Egg-Yolk* methods are applied to study geographies with unclear boundaries. Though these methods intuitively use approximation, it is not similar to the partitioning in RST based on equivalence classes. Further, egg-yolk method is reported to have performance issues when continuous space is involved. Beaubouef (1994) proposed rough set version of *RCC* and *Egg-yolk* and recorded better observations. The paper discusses modelling boundaries of Spatial Regions using RST where each grid of spatial data is considered as an equivalence class. Low resolution means coarser boundary region and vice-versa is also true. Modelling of topological features has been highlighted. Out of the eight relations that *RCC* encompasses, five are applicable to Lower Approximation that should be a subset of Upper Approximation. However, spatial auto correlation is not addressed in this paper.

Wang (2004) demonstrated rough interpretation and introduced the idea of rough topological space and relationships between the attributes. The work has suggested handling uncertain data without coercing them to crisp data. The work recalls various approaches like evidence theory, cloud theory, error band, epsilon band and others are used to handle some parts of uncertainty in data. As part of rough spatial interpretation, this work explores the probabilistic rough set defined by a membership function $\mu_x(x)$ where its value ranges from 0 to 1. A rough spatial entity is characterised by a pair of upper and lower approximation. Rough vector space to define a point, line or area is used and a raster space for shapes and forms. This helps in translating real world coordinates to computer screen coordinates. The approach also helps in image resolution features. Further, rough topology for relationships between spatial entities is also defined as rough relation between crisp-crisp, rough-crisp and rough-rough

entities. This *rough spatial interpretation* is used by Murgante et al.(2007) to define periurban fringe. The term *periurban fringe* is defined with respect to the inclusion (proximity to cities, population distribution etc.,) and exclusion (erosion, landslide area etc.,) of innate organic rules. He has compared the analysis from Map Algebra and Spatial Rough Sets and recorded that the latter has delivered improved interpretation.

Rough Sets Based Decision Systems for Spatial Data Analytics

Mining spatial rules has been the objective in a majority of work done with respect to spatial data. A decision system with a set of objects, conditional and decision attributes is constructed. It is defined as $(U, CA \cup DA)$ where U is the universe of non-empty objects, CA are the conditional attributes and DA the decision attributes. Construction of the decision requires understanding of the nature of objects we deal with. The attributes may be of crisp or fuzzy nature. There may be indiscernible objects in the universe. If we base the decision system on rough sets, equivalence classes based on equivalence relation are found and an associated indiscernibility is defined. The objects that belong in an indiscernibility relation are similar to each other with respect to the attributes based on which equivalence relation is defined. For any subset $X \subseteq U$ and any $F \subseteq CA$, is an associated equivalence relation $IND_s(F) = \{(x, x') \mid \forall a \in F, a(x) = a(x')\}$, called *F-indiscernibility* relation. The equivalence class of this is specified as $[x]_F$. Lower and upper approximations of X with respect to F are defined as $\underline{F}X$ and $\overline{F}X$ where $\underline{F}X = \{x \mid [x]_F \subseteq X\}$ and $\overline{F}X = \{x \mid [x]_F \cap X \neq \emptyset\}$. The difference of these two sets is the boundary set. A set is rough if the boundary region is not empty.

Also, the number of attributes involved may be very large. The attributes that preserve indiscernibility relation are retained. This is achieved by

identifying *reduct* and *core* in RST. Thangavel and Pethalakshmi (2006) proposed Reduct algorithm for feature selection, also other variants, genetic algorithm based reducts etc., are available to identify reducts. This ensures that classificatory performance of reduced set of attributes is same as the original set. After identifying the reducts, decision rules are extracted.

Usually, continuous attributes have to be discretized in the rough set based decision system to establish indiscernibility. But in the case spatial data, continuous values may have to be preserved to avoid loss due to generality.

NEIGHBOURHOOD ROUGH SETS

Neighborhood system was introduced for the study of Fechet (V) spaces, which are convex vector spaces used for representing multi-dimensional features. Lin (1988) later used it to study relationships between objects. Yao (1999) generated the idea of knowledge granulation structures from it. For a given object x in the universe U , a Neighborhood is associated with it called $n(x)$ which is a *subset* of U . If $n(x)$ includes x , it is a reflexive Neighborhood. A Neighborhood system $NS(x)$ of x is defined as a non-empty family of Neighborhoods of x and is denoted as $NS(x) = \{(x)_R\}$ from U/R where R is a reflexive relation. Approximations are defined by constructing a covering of the universe with all Neighborhoods in $NS(x)$. Neighborhoods are defined using nearest neighbour methods or by distance from central point to boundary. Using the latter method, for a given set of continuous attributes in space, a Neighborhood is defined for every object in U , as $\delta(x) = \{y \mid x \in U, d(x, y) \leq \delta\}$ where $\delta > 0$ and $\delta(x)$ is δ Neighborhood information granule of x . Neighborhood approximation is applied to identify the positive and boundary region. The set of objects in the positive region are identified into decision classes without ambiguity.

Non-spatial attributes can be reduced to core attributes using rough set approximation concepts. The minimal *reduct* induced can be intersected with the attributes determined using Neighborhood Rough Sets from which the rules can be inferred. Treating the spatial and non-spatial attributes separately and integrating them later will uphold the inherent spatial features critical to the semantics of rules.

Suitability of Neighborhood Rough Sets for Spatial Data

Spatial Data: Continuous

Spatial data involves attributes like temperature, rainfall, slope, humidity and generally are continuous and involve real number space. Discretising them may lead to loss of information.

Continuous attributes are modelled based on the domain expertise, transformation using discretization to fit decision systems or using Neighborhood relations. Use of domain expertise may not be a common approach and inevitably requires ways to ensure authentication. This may be an overhead in most of the cases. Discretization of continuous values is recorded to have loss of generality in some cases. In the context of Spatial Decision System, the continuous values of attributes are to be preserved. Neighborhood systems use similarity metric to relate data and reduce the chances of information loss.

Lin.T. Y (1989) used neighborhood system or topology to formalize approximation in relational databases. The work further states that neighborhood systems can be used for approximation in numerical analysis for which a neighborhood of tolerance has to be identified even before the approximation commences.

Neighborhood structure can be used for continuous attributes represented in the decision system. Nearest neighbour and distance measure are used in Neighborhood systems of which the latter can be used for handling continuous spatial data.

Spatial Auto Correlation

Spatial correlation is the feature where the values for an attribute will tend to be similar or vary in the order of small gradients in a geographic area. Spatial features like temperature, rainfall, humidity etc., are some of the examples. It will be significant to the decision rules generated if this correlation is upheld while partitioning. Neighborhood Rough Sets is a favourable candidate which does not discretise the attribute values to induce partitioning.

Neighborhood Based Coverings

The classical rough set theory induces the partitioning of universe based on equivalence relations. The approximations (lower and upper) generated by partitions will be vary according to partitions whereas in a covering based scenario, different coverings may induce the same approximations. Yao (1999) proposed neighborhood systems and augmented that it is covering based. It generates closely related covers which will be conducive for continuous values. Although, there is redundancy to be considered in the case of covering, as removal of a data item will leave the partition incomplete (because the partitions are based on equivalence relations). This may not happen in the case of Neighborhood based coverings.

NEIGHBORHOOD GRANULATION

Definition 1: Given an N dimension real number space U , two objects $x_i, x_j \in U$, the distance metric δ between the two data objects, then following properties are satisfied in the neighborhood model.

$$\delta(x_i, x_j) \geq 0, \text{ iff } i = j, \delta(x_i, x_j) = 0 \quad (1)$$

$$\delta(x_i, x_j) = \delta(x_j, x_i) \quad (2)$$

$$\delta(x_i, x_j) + \delta(x_j, x_k) \geq \delta(x_i, x_k) \quad (3)$$

Then we called (U, δ) is a real number space. The above three properties are reflexivity, symmetry and non-transitive properties of neighborhood relation.

Definition 2: Given a finite set of objects $U = \{x_1, x_2, x_3, \dots, x_n\}$ in real number space, for every object x_i in U , then the δ -neighborhood definition is as follows:

$$\delta(x_i) = \{x | x \in U, d(x, x_i) \leq \delta\} \quad (4)$$

where $\delta > 0$, $\delta(x_i)$ is δ neighborhood information granulation from x_i and called as x_i neighborhood granulation.

Neighborhood relations are a kind of similarity relations, which satisfy reflexivity and symmetry properties. The data objects are drawn together for similarity in terms of distances and the samples in the same neighborhood granule are close to each other. Considering two x_i, x_j objects in a M-dimensional space with attribute set $A = \{A_1, A_2, \dots, A_M\}$, $f(x, A_i)$ represents the value of object x in attribute A_i , a Minkowsky distance defined by

$$\delta_p(x_i, x_j) = \left(\sum_{i=1}^M |f(x_i, A_i) - f(x_j, A_i)|^p \right)^{1/p} \quad (5)$$

$\delta_p(x_i, x_j)$ is Manhattan distance if $p=1$, Euclidean distance if $p=2$ and Chebychev distance if $p=\infty$. Distance functions are discussed by Wilson & Martinez (1997) in detail. $\delta_A(x_i)$ is

the neighborhood of data object x_i and its size is based on the threshold δ .

Spatial attributes exhibit spatial auto correlation, where the values for an attribute tend to be similar in a geographic neighborhood. This is measured using Moran's Index in a Geographic Information System (GIS). This index can only compute autocorrelation of numerical data and not that of categorical data. Using neighbourhood granulation to calculate autocorrelation addresses this issue. Appropriate distance measure can be used to calculate neighbourhoods or spatial autocorrelation of numerical, categorical and mixed data.

Considering Table 1, we can calculate the neighborhood of objects in an attribute, for e.g. slope. We decide on a neighborhood threshold 0.2.

$$\delta(z1) = \{z1, z2, z5, z7\}, \delta(z2) = \{z1, z2, z7, z8\}, \\ \delta(z3) = \{z3, z8\}, \delta(z4) = \{z4\}$$

$$\delta(z5) = \{z1, z5, z6\}, \delta(z6) = \{z5, z6\}, \\ \delta(z7) = \{z1, z2, z7, z8\}, \delta(z8) = \{z2, z3, z8\}$$

If we need to calculate the neighborhood across two attributes which are numerical, *Euclidean* distance can be used. For attributes of categorical or mixed, suitable distance measures can be used as discussed in Wilson & Martinez (1997).

Neighborhood Approximation

Considering a set of objects $U = \{x_1, x_2, \dots, x_n\}$, a neighborhood relation R , then the neighborhood approximation space $S = \{U, R\}$ and for any $X \subseteq U$, lower and upper approximations are defined as follows:

$$\left\{ \begin{aligned} \underline{R}X &= \{x_i \in U | \delta(x_i) \subseteq X, x_i \in U\} \\ \overline{R}X &= \{x_i \in U | \delta(x_i) \cap X, x_i \in U\} \end{aligned} \right\}$$

The positive, negative and boundary region are as follows:

$$\begin{cases} POS(X) = \underline{R}X \\ NEG(X) = \sim \bar{R}X \\ BND(X) = \bar{R}X - \underline{R}X \end{cases}$$

A data object will fall in positive or boundary region. Also, roughness of subset X in the approximation space is inferred from the size of boundary region. The set of objects in positive region can be classified with certainty while the objects in boundary region will have indeterminate classification.

CONCLUSION

Rough sets and its variants have been used in mining decision rules in a number of applications. Use of rough sets in spatial data mining and its relevance has been discussed in the chapter. Considering Neighborhood Rough Sets based decision system for spatial data mining will help in avoiding the loss of information. The decision attributes in spatial decision system are considered to be crisp. Bai & Ge (2010) proposed Rough Fuzzy approach to spatial decision attributes. This was to accommodate a range of memberships for decision attributes with which real world scenario can be better represented. Using Neighborhood Rough Sets helps in preserving the continuous nature of spatial data and the inherent spatial autocorrelation without which these real world features might be overlooked in the decision system.

FUTURE WORK

More work can be carried out to study the potential of Rough Fuzzy and Rough Intuitionistic Fuzzy

System with Neighborhood Systems in constructing decision systems and evaluation of rules generated. NRST based Approximation strategies can be tested on various domains and compared with RST approximations. Variants involving tolerance relations can be studied. Identifying reducts for Neighborhood Rough Sets can be studied further. Rule generation and learning for NRST can be analysed and validated for various domains.

KEY TERMS AND DEFINITIONS

Categorical Data: Data grouped to form a category when numerical representation is not adequate.

Distance Measure: Measures to calculate distance between numerical, categorical or mixed data.

Granulation: It is using groups or clusters of data objects formed on the basis of similarity in an incomplete information system.

Neighborhood Systems: They provide granulation structure for each element of a universe.

Rough Sets: An extension of classical set theory, which provides an approximation of crisp set in terms of lower and upper approximation.

Spatial Auto Correlation: The values of a spatial attribute tend to be close to each other and vary gradually from core to periphery of a geographic region.

Spatial Data Mining: Mining patterns or rules from spatial data with respect to a geographic reference.

The Ontology of Randomness

D

Jeremy Horne

The International Institute of Informatics and Systemics, USA

INTRODUCTION

“Random” commonly is associated with determinism, order, prophecy, and the future. Starkly put by one philosopher, “Randomness is unpredictability” (Eagle, 2005), quoting mainstream logician Suppes in saying “Phenomena that we *cannot predict* must be judged *random*” (Suppes, 1984, p. 32). People rely upon uncertainty (encryption and defeating bias). Tables of random numbers are based on the supposition that humans subconsciously create patterns and cannot generate randomness. Gambling casinos are about the “luck of the draw”. Human survival depends on remembering patterns of past events in order to adapt to the changing environment, as well as on randomness in science.

Our focus is not only on considering whether randomness exists, i.e., ontology, but the reason for it. Turmoil in the field of experts is expressed by “... there is no such thing as a random number - there are only methods to produce random numbers...” (Von Neumann, 1951; Fiorini and De Giacomo, 2014, p. 5). How can one create something that cannot exist? Yet, at the most basic building block level of existence, Planck scale, there is inherent uncertainty (perhaps immanent in the macro world) with which persons have difficulty accepting.

A new view of randomness will be presented here, based on the often neglected philosophy of dialectics, apprehension of something in terms of what it is not, a process understanding, rather than one of identifying objects.

This short space allows only a small sampling of approaches to the ontology of randomness for the reader to explore in depth through cited references. If one can begin to think beyond the

mechanics (as in random number generators) then this encyclopedia entry will have accomplished its purpose.

BACKGROUND

The Ontology of Randomness in this *Encyclopedia of Information Science and Technology*, focuses more on the thinking underpinning science, more specifically, whether randomness even exists, i.e., its ontology (Feibleman, 1951). Tests for randomness appear to assume what is trying to be shown, i.e., there is indeed randomness, begging the question of whether there is innate structure, or order, in the universe.

Because of very limited space, extended tutorials and discussions about ontology (the nature of existence), epistemology (how we know), the problems of induction (Hume, 1888; Mill, 1843; Russell, 1919; Ramsey, 1929; Keynes, 1921, pp. 305-314; p. 24 et seq.), stochastic analysis (series of random variables), and the problems of representation (Plato’s cave allegory as the philosophical foundations of statistics) have been omitted. Also omitted is a discussion of the role of randomness in logical scientific exploration (Popper, 1934; hypothetico-deductive, 2015; Copi, 1979; Rosser, 1953; Mendelson, 1997; Whewell, 1847; Feyerabend, 1975), as well as discussions of Abraham de Moivre (bell curve), Pierre-Simon Laplace (calculus of probabilities), and martingales (Birnbaum and Lukas, 1980). There are many other conversations about the differences between probability, chance (Keynes, 1921; Eagle, 2010), and randomness that would enrich a more complete treatment of the subject. This says nothing of the hundreds of mainstream

DOI: 10.4018/978-1-5225-2255-3.ch161

works of probability theorists and their views on randomness. Instead, given here is somewhat analogous to a brief literature search, with a focus on summarizing several main views of what people think randomness is and considering the implication of its existence status. If such can get the reader to think beyond technology, focusing more on the “why”, then this chapter will have accomplished its goal.

A Historical Perspective

Prediction for an early hunter meant being able to survive any challenge in the wild, that ability being taught to others. One thinks of shamans, soothsayers, and prophets being among the more esteemed members of various cultures.

Randomness came in the form of early games (Wolfram, 2016), a symbolized way of acting out in anticipation of meeting unpredictable events. As societies became more organized, those more skilled in correctly anticipating events led the military. Athletic competitions and often games emerged as simulations of military combat (History of Sport, 2016). In modern times, sophisticated modeling and simulation techniques describe, analyze, and plan for unexpected situations (MSBOK, 2016).

Current Views of Randomness

For the general public, “random” and its derivatives are defined variously as:

- “...proceeding, made, or occurring without definite aim, reason, or pattern”. (Random - Dictionary – Random House, 2016).
- “...the lack of pattern or predictability in events”. (Randomness - Wiki, 2016).
- “...without definite aim, direction, rule, or method; lacking a definite plan, purpose, or pattern”. (Random - Dictionary – Webster, 2016).

- “... Made, done, happening, or chosen without method or conscious” (Random - Dictionary - Oxford American, 2016).

More formally but non-exhaustive are the main areas of:

- Relative frequency concept of probability;
- Information complexity/compressibility of information – Chaitin-Kolmogorov-Smirnov-Shannon;
- Predictability and probability;
- Energy – Boltzmann-Clausius – entropy;
- Observation about completeness and certainty – Heisenberg, Gödel.

All of these overlap but have in common the inability of discerning future specificity, i.e., uncertainty. Following is a brief sketch of these views.

Relative Frequency Concept of Probability

Von Mises probability centers on “relative frequency”, the ratio of appearances of an attribute in an event to the total number of events (as in how a color of a flower varies in a seed type, the number of dots shown with each roll of dice, or the number of deaths in an age group) (Von Mises, 1957, p. 11). As more events are observed the ratio becomes more refined, or more stabilized (.5,.51,.519,.5196, etc.)(Ibid., pp. 14-15). A “collective” is a “sequence of uniform events or processes which differ by certain observable attributes, i.e., a set of events from which a certain characteristic is to be observed” (Ibid., p. 12). Probability is the likelihood of “...encountering a certain attribute in a given collective” (Ibid.). Further, it is the “...limiting value of the relative frequency in a true collective which satisfies the condition of randomness” (Ibid., p. 24).

A “true” or “collective appropriate for the application of probability” must indeed have

limiting values that “remain the same in all partial sequences which may be selected from the original one in an arbitrary way” (Ibid., pp. 24-25). So, if all the odd numbered elements are selected or ones designated by a prime number, the selection of this partial sequence being before the relative frequency is known, this “place selection” (deciding “whether an element should or should not be included” (Ibid.) regardless of the element’s attribute) will exhibit that relative frequency. That is, putting a member of the original sequence in the “selected partial sequence” is to be done apart from observing the value of the relative frequency. All sequences, then, should exhibit the same relative frequency, the observation being done after all the partial sequences have been identified. Randomness, then, is place selection on this basis.

Information Complexity/ Compressibility

If we cannot say what has generated a string of characters (method) that string is random, a view held by Kolmogorov (Kolmogorov complexity) and Chaitin (information compressibility), often combined as “Kolmogorov–Chaitin complexity, algorithmic entropy, or program-size complexity” (Kolmogorov complexity, 2016).

Kolmogorov (1998) argues that von Mises’ frequency view cannot be applied as probability theory to actual situations where there are to be a certain number of trials. While basically sound it also is not amendable to a rigorous pure mathematical analysis; there needing to be a way of measuring the algorithm’s complexity. Formally stated:

$$T = (t_1, t_2, \dots, t_n)$$

of N zeros and ones: $t_k = 0$ or 1 .

Such a table will be called random, if, while choosing the subset A of sufficiently large size from $1, N$ by different methods there is stability in the frequency

There is stability in the frequency

$$\pi(A) = 1/n \sum t_k$$

$$k \in A \quad (\text{Kolmogorov, 1998, p. 388})$$

Chaitin (1975, 1998), very much like Kolmogorov, says, “something is random if it is algorithmically incompressible or irreducible. More precisely, a member of a set of objects is random if it has the highest complexity that is possible within this set.” (Chaitin, Randomness, 1975, p. 71).

For example,

010101010101010101

01101100110111100010
